ACKNOWLEDGMENTS

The Arcata Fish and Wildlife Office (AFWO) wishes to acknowledge the Karuk Tribe of California, Department of Natural Resources, for providing support and the following personnel: Ron Reed, Mike Polmateer, and Dave Arwood II. In addition, we are grateful to Tom Shaw and George Guillen for editorial comments. We would also like to thank Wally Johnson for allowing us river access through his property at Seiad.

ABSTRACT

This report describes observations and results of the ninth annual U.S. Fish and Wildlife Service fall chinook salmon (*Oncorhynchus tshawytscha*) spawning survey on the mainstem Klamath River. The survey was conducted for eight weeks from October 15 to December 14, 2001, covering 134.8 river kilometers (83.8 river miles) between Iron Gate Dam and the confluence of Indian Creek at Happy Camp. A total of 2,172 redds were observed during the 2001 survey which represents a 38% increase from the 2000 redd count, and the second consecutive year of increasing redd numbers since 1997.

In 2001, spawning was observed throughout the mainstem Klamath River from Iron Gate Dam to Indian Creek with 38% (n=830) of the redds located between Iron Gate Dam and the Shasta River. From 1993 to 1999, the tendency for chinook to spawn within the upper 10 river km (rkm; Iron Gate Dam to Cape Horn Creek), increased from 24.2 to 60.9%, but in 2000 decreased to 37.5%. In 2001 this number decreased once more to 25.8%. Redd density in this upper mainstem section was 56.1 redds/rkm. The lowest redd densities in 2001 were between Shinar and China Creek (4.3 redds/rkm). Water clarity between Iron Gate Dam and Indian Creek ranged from 1.2 to 3.0m, and represented some of the highest visibility recorded for these surveys.

During 2001, only one redd was observed on a suction dredge tailing between Iron Gate Dam and Indian Creek.

INTRODUCTION

The Klamath River drains approximately 14,000 km² in Oregon and 26,000 km² in California. The majority of the watershed in California is within the boundaries of the Six Rivers, Klamath and Shasta-Trinity National Forests. The Yurok Indian Reservation, comprising approximately 139 km² in Humboldt and Del Norte counties, borders the lower 68 km of the Klamath River (Figure 1). The most important anadromous salmonid spawning tributaries in the basin include the Trinity River (the largest tributary in the basin) draining approximately 7,690 km², and the Shasta, Scott and Salmon rivers, each draining approximately 2,070 km². Iron Gate Dam (IGD; rkm 306, rm 190.1) on the Klamath River and Lewiston Dam (rkm 249, rm 154.7) on the Trinity River represent the upper limits of anadromous salmonid migration in the basin. Iron Gate Hatchery (IGH) and Trinity River Hatchery, located near the base of each dam, were constructed as mitigation for natural fish production losses resulting from each project (USFWS 1991).

The Klamath River Basin has historically supported large runs of chinook salmon (*Oncorhynchus tshawytscha*), coho salmon (*O. kisutch*), and steelhead trout (*O. mykiss*), which have contributed considerably to subsistence, sport and commercial fisheries in California. Generations of Indians have utilized fishing grounds in the drainage, and their fisheries for salmon, steelhead and sturgeon have historically provided the mainstay of the Indian economy in the area. Sport fishing for salmon and steelhead in the drainage may exceed 200,000 angler days annually. During the 1980's, the Klamath River stocks accounted for up to 30% of commercial chinook salmon landings in northern California and Southern Oregon and averaged 450,000 chinook per year (PFMC 1988).

Concern about the depletion of anadromous salmonid resources and associated habitat in the basin emerged around the turn of the century, and has accelerated in recent decades coincident with expanded logging and fishing operations, dam building activity, road construction and other development. As in other river systems of the Pacific Northwest, chinook salmon of the Klamath River Basin have experienced the continued effects of habitat degradation and over-exploitation as reflected by declining runs in recent decades (USFWS 1991).

On October 27, 1986 the Congress enacted P.L. 99-552, the Klamath River Fish and Wildlife Restoration Act. This action authorized the Secretary of the Interior to restore the anadromous fish populations to optimum levels in both the Klamath and Trinity Rivers through a habitat restoration program and formation of the Klamath River Fishery Management Council (USFWS 1991).

The U.S. Fish and Wildlife Service (USFWS) was funded through the Klamath River Fish and Wildlife Restoration Program to identify fall chinook spawning areas and collect information necessary to estimate the natural fall chinook spawning escapement on the mainstem Klamath River between IGD and the confluence of Indian Creek. This information is critical for the evaluation of instream flow and harvest management alternatives.

MATERIALS AND METHODS

Survey Procedures

The Arcata Fish and Wildlife Office (AFWO) mainstem Klamath River redd survey protocol consisted of six mainstem reaches (Figure 2) covering 134.8 rkm (83.8 river miles). The six reaches were surveyed weekly from IGD to the confluence of Indian Creek, unless adverse weather limited the visibility of the water to less than one meter in depth. The reaches were surveyed between October 15 and December 14. Two individual crews were organized for conducting the survey. Each crew covered the same survey reaches each week to remain familiar with each survey reach and prior redd locations.

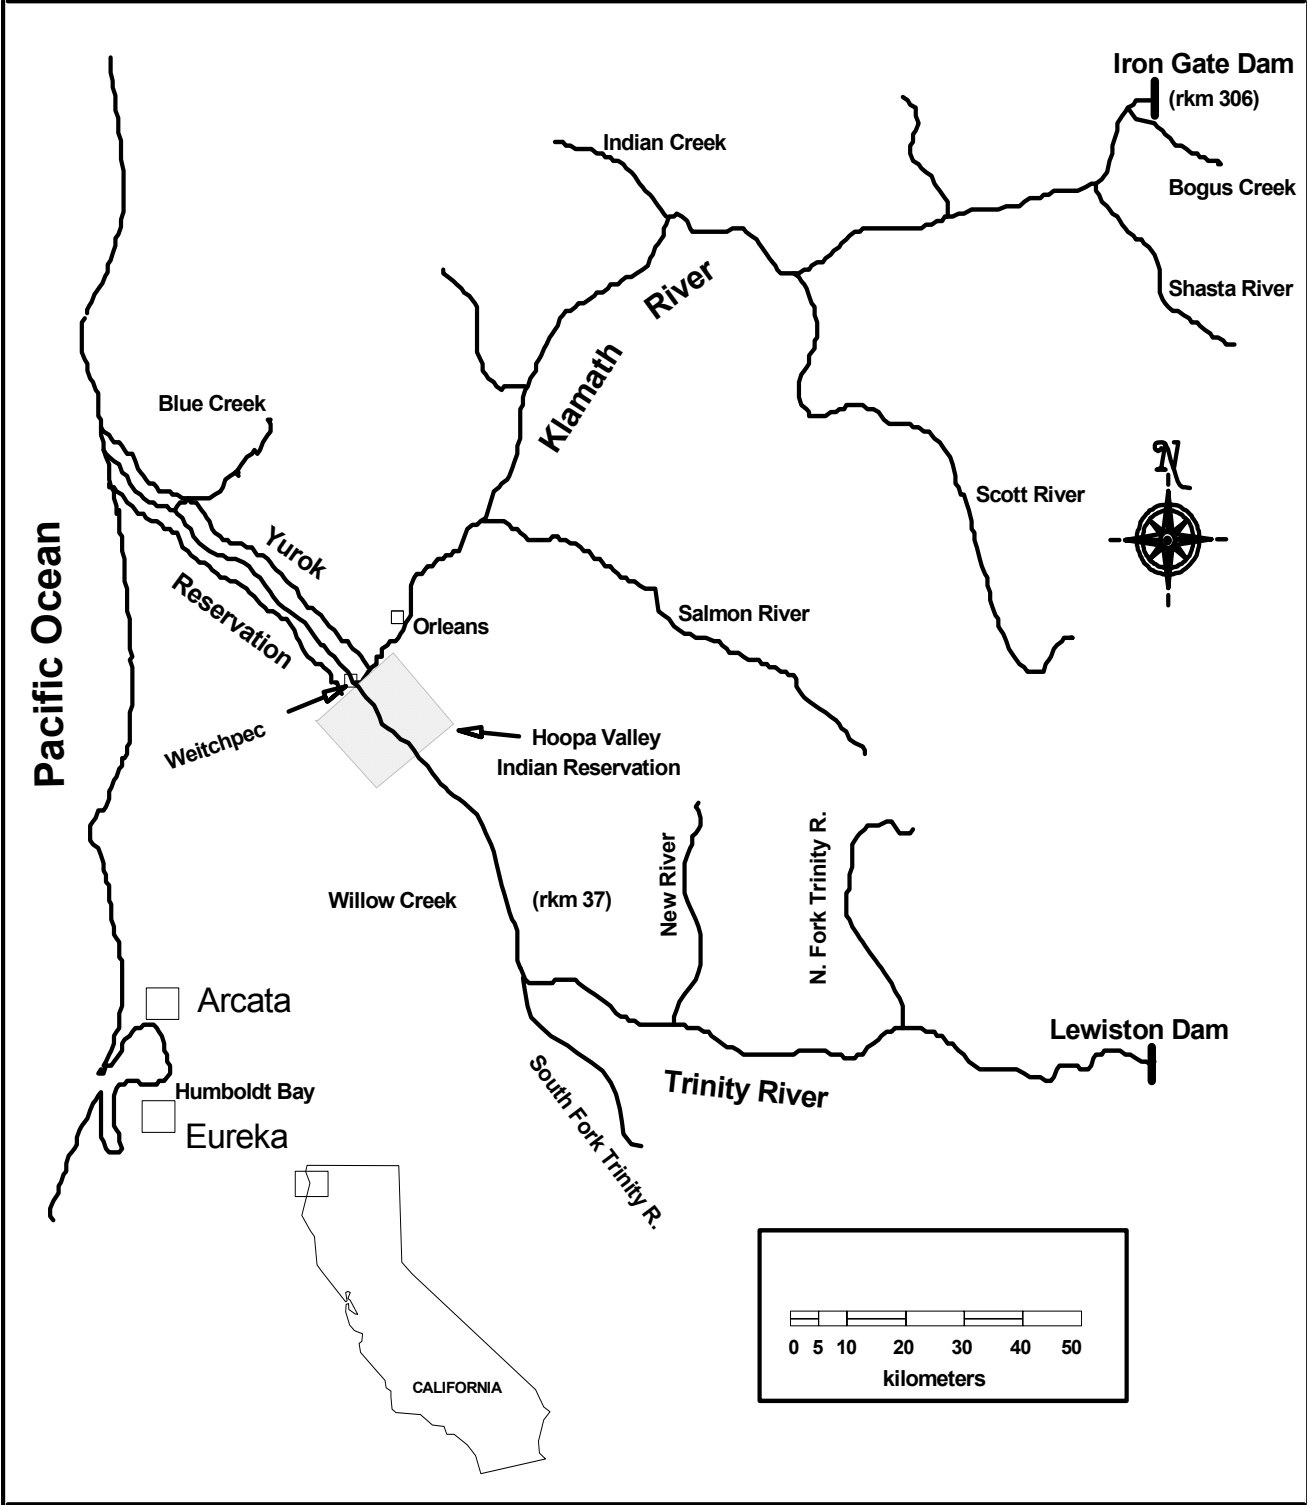

Figure 1. Overview map of the Klamath River Basin accessible to anadromous fish.

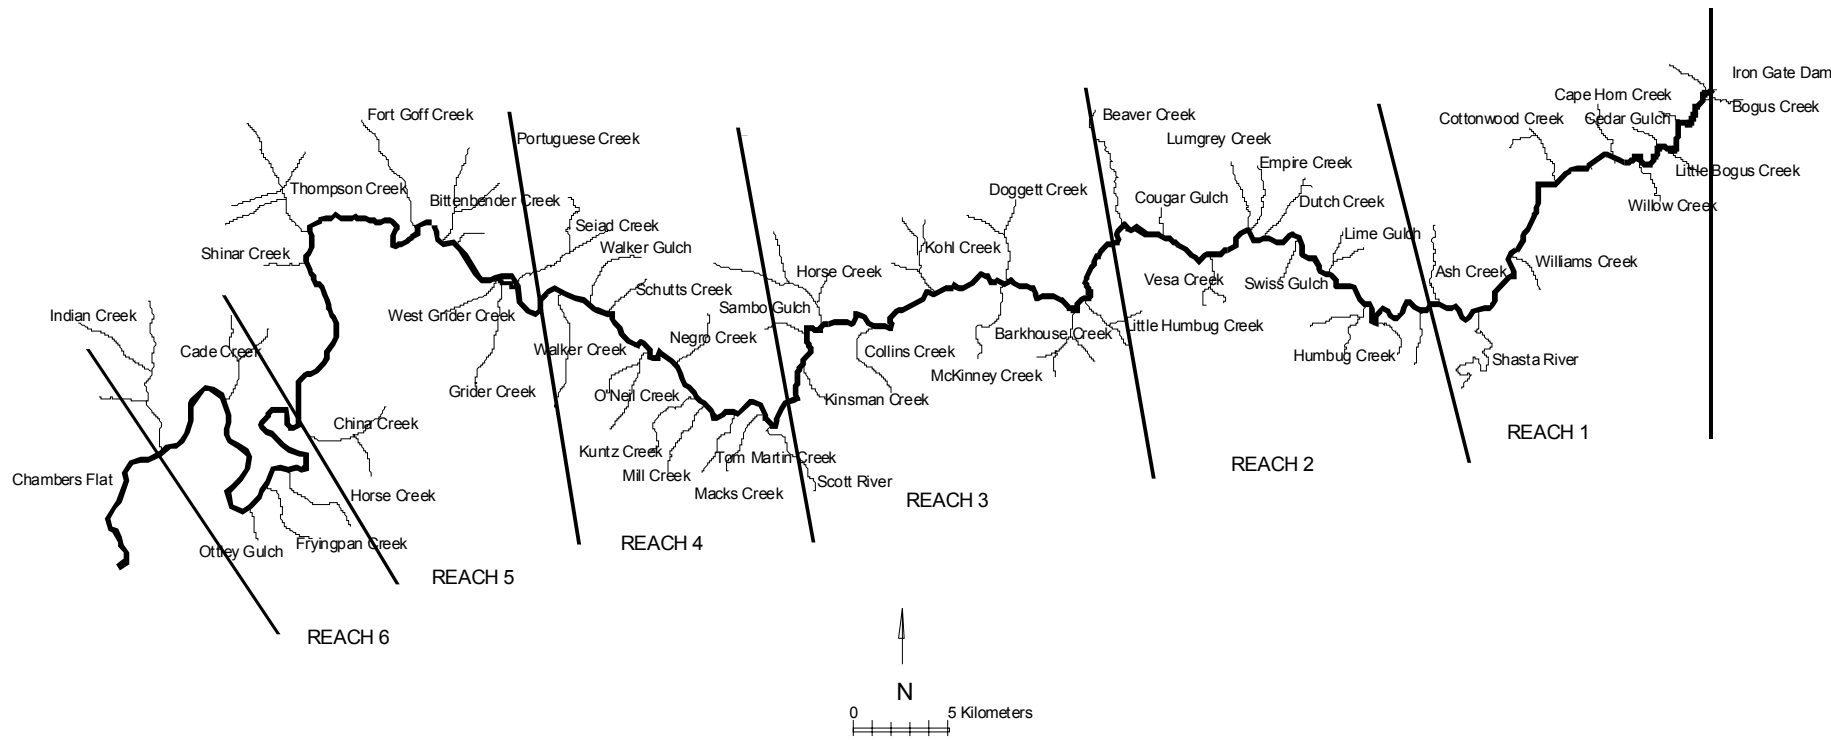

Figure 2. Mainstem Klamath River chinook spawning survey project location including individual study reaches (1 to 6).

Rafting Equipment

Two 4.27 m (14 foot) inflatable Wing Cataracts were used for direct observation of fall chinook salmon redds. These rafts are commonly used for use in white water rescue due to their stability and maneuverability in fast water. The rafts were stacked on a flat bed trailer and deployed at selected access sites along the study area. Each raft was equipped with a rowing frame, a modified observation platform, and anchoring system. Two personnel operated each raft (rower and observer).

Survey Equipment

Plastic survey flagging tape was used to mark individual redds and redd clusters along the river bank in each reach. Polarized sunglasses and baseball style caps were used to reduce glare and improve visibility into the water. A removable wooden measuring rod (2.4 m) was mounted upright on each cataract to help observers balance while standing up and to measure redds. During the sixth (November 26 to 30), seventh (December 3 to 7) and eighth weeks (December 10 to 14) of the survey, crews marked the location of individual and redd clusters with a Garmin Global Positioning System (GPS) Receiver.

Reaches 1 to 6

Reach 1: IGD river access (rkm 306.1) to Ash Creek river access (rkm 281.6; Figure 2).

Reach 1 is approximately 24.5 rkm (15.2 miles) in length and was surveyed over a period of two days (Monday and Tuesday). Due to the high percentage of redds in Reach 1, two cataract crews surveyed the entire reach from IGD to Deliverance Camp river access (rkm 283.1). One crew surveyed the left bank to mid-channel while the second crew surveyed from the right bank to mid-channel. A section of Reach 1 from the Interstate 5 (I-5) bridge (rkm 288.4) to the Deliverance Camp river access (rkm 283.1) was completed in approximately two hours on the first day (Monday) during weeks 1 to 6. The section from Deliverance Camp river access to Ash Creek river access (rkm 281.6) was not surveyed because past surveys have revealed lack of available spawning habitat. On the second day (Tuesday), the survey resumed from the IGD river access to the I-5 bridge. This section was completed in eight to ten hours and was surveyed each week for 6 consecutive weeks. This section was also surveyed the sixth week to finish recording redd locations with a GPS.

Reach 2: Ash Creek river access to Beaver Creek riffle river access (rkm 257.1; Figure 2).

Reach 2 is approximately 24.5 rkm (15.2 miles) in length. The Beaver Creek riffle river access is located along the right bank on a large gravel bar downstream from Beaver Creek bridge, just off Highway 96. One crew surveyed this reach, on the third day (Wednesday) in approximately seven hours. Reach 2 was surveyed each week for five consecutive weeks. Reach 2 was surveyed once more during week eight in order to record redd locations with a GPS.

Reach 3: Beaver Creek river access to Blue Heron river access (rkm 230.0; Figure 2).

Reach 3 is approximately 27.1 rkm (16.2 miles) in length. The Blue Heron river access is approximately 2 rkm upstream from the Scott River confluence. This reach was surveyed by one crew on the third day (Wednesday) in approximately eight hours. Reach 3 was surveyed each

week for five consecutive weeks. Reach 3 was surveyed with GPS during weeks seven and eight.

Reach 4: Blue Heron river access to Seiad Bar river access (rkm 211.2; Figure 2).

Reach 4 is approximately 18.8 rkm (11.3 miles) in length. The Seiad Bar river access is located along the right bank of the Klamath River. River access was acquired approximately 2.7 rkm downstream of the access point used in past spawner surveys. The river access is acquired by taking the road to the right of the California Department of Transportation's compound. The reach boundaries remain the same as those from past years. This reach was surveyed on the fourth day (Thursday), by one crew, in approximately eight hours. Reach 4 was surveyed each week for five consecutive weeks. Reach 4 was surveyed once more during week eight to record redd location with GPS.

Reach 5: Seiad Bar river access to China Point river access (rkm 188.5; Figure 2).

Reach 5 is approximately 22.7 rkm (13.6 miles) in length. China Point river access is located along the right bank of the river, at the U.S. Forest Service (USFS) river access just off Highway 96. One crew surveyed this reach, on the fourth day (Thursday) in approximately seven hours. Reach 5 was surveyed each week for five consecutive weeks. Reach 5 was surveyed with a GPS unit during week eight to record redd locations.

Reach 6: China Point river access to the Indian Creek confluence (rkm 169.4; Figure 2).

Reach 6 is approximately 19.1 rkm (11.4 miles) in length. Due to the high concentration of redds in this area, this reach was split at Gordons Ferry river access (rkm 180.4). China Point river access to Gordons Ferry river access is approximately 7.2 rkm (4.5 miles). Gordons Ferry river access to Indian Creek confluence is approximately 11.5 rkm (7.1 miles). The Gordons Ferry river access is located just off Highway 96. This reach was split into two sections and covered by two crews on the fifth day (Friday) with each section taking approximately five hours to survey. Reach 6 was surveyed for four consecutive weeks and on week seven redds were recorded with a GPS unit.

Distribution of Redds :10 km Sections

In order to describe the frequency of spawning redd occurrence, in percentages, by yearly redd counts, the mainstem Klamath River between IGD and the confluence of Indian Creek was broken into 14 river sections approximately 10 rkm long.

Collection of Redd Data

The date, number of redds per site, location in channel, and redd site tally number were recorded on each flag. Flags were tied to the bank nearest the redd. A different color flagging was used each week to ensure that redds were not double counted during the course of the survey. Redd sites were also recorded on river maps and on data forms. Data recorded included: GPS mark number, tally number, location in channel (left or right bank, middle, side channel, split channel and pool tail-out), distance from bank, defended area (distance between redds in a cluster), number of adults and grilse, flag location, water temperature, weather conditions, river reach, and age of redd code. Estimated redd ages were recorded as Redd Age Code 1, 2 or 3 depending

on appearance. Fresh redds with bright substrate, little or no periphyton, and well-developed mounds were classified as Redd Age Code 1. Redds two to four weeks old with slightly flattened mounds and dulled substrate due to periphyton growth were classified as Redd Age Code 2. Redds older than four weeks, which were identifiable only by pit and/or mound presence and typically could not be distinguished from surrounding substrate by brightness differences, were classified as Redd Age Code 3. Only completed redds (which included both a pit and mound) were included in the daily counts. Test redds and small (<1.0 m²) redds were omitted.

Water Temperature

Water temperature was recorded using an Optic Stowaway Tidbit on an hourly basis throughout the survey period at the downstream end of R-Ranch (5.5 rkm downstream of IGD). Hourly data was used to calculate the mean daily water temperatures.

Discharge

Mean daily river flow was provided by the U.S. Geological Survey gaging station (Number 11516530), located in the Klamath River just downstream of IGD. Daily river flow was recorded in cubic feet per second (cfs)

Water Clarity

A 20 cm diameter Secchi disc was used daily throughout the surveys to measure water clarity. Water clarity was measured by lowering a Secchi disc vertically into the water column. The disc was lowered until the black and white pattern on the disc was not discernable. The disc was then raised until the pattern was just vaguely discernable, and this depth was recorded in meters.

Adult Grilse Expansion

The total number of redds counted by AFWO during these surveys is used by California Department of Fish and Game (CDFG) to estimate adult and grilse (two year old) spawning abundance (Sinnen 2002). Adult numbers were calculated by multiplying the total redd count by two. This estimate assumes there is only one male and female salmon per redd. The total number of grilse was estimated from length frequency and scale analysis data.

RESULTS AND DISCUSSION

A total of 2,172 chinook salmon redds were counted between IGD and the confluence of Indian Creek, representing a 37.6% increase from the 2000 count of 1,578 (Table 1). From 1993 to 2001 effort on the reaches has not been consistent (Figure 4). Based on field maps and notes from the survey, locations of redds for all reaches surveyed are shown in Figures 6-9.

Reaches 1 to 6

Reach 1: IGD to Ash Creek river access.

A total of 830 redds were observed in this reach during the 2001 survey (Table 1; Figure 6). The 830 redds represent 38.2% of the total redd count for 2001. The redd density in this reach was 33.9 redds/rkm (Figure 3). Based on weekly redd counts, peak spawning (n=323) occurred during Week 3 (Table 1).

Reach 2: Ash Creek river access to Beaver Creek Riffle river access.

A total of 269 redds were observed in this reach during the 2001 survey (Table 1; Figures 6 and 7). The 269 redds represent 12.4% of the total redd count for 2001. Redd density was 11 redds/rkm (Figure 3). Peak spawning (n=102) occurred during Week 2 of the survey (Table 1). The 269 redds counted in this reach represent the highest count since the project started in 1993 (Table 1).

Reach 3: Beaver Creek Riffle river access to Blue Heron river access.

A total of 435 redds were counted in this reach during the 2001 survey (Table 1; Figure 7). The 435 redds represent 20% of the total redd count for 2001. Redd density was 16.1 redds/rkm (Figure 3). Peak spawning (n=170) in Reach 3 occurred during Week 3 (Table 1). The 435 redds observed during the survey is the highest count for this reach since the project started in 1993.

Reach 4: Blue Heron river access to Seiad Bar river access.

A total of 220 redds were counted in this reach during the 2001 survey (Table 1; Figures 7 and 8). The 220 redds represent 10.1% of the total redd count for 2001. Redd density was 11.7 redds/rkm (Figure 3). Peak spawning (n=102) in Reach 4 occurred during Week 3. The 220 redds observed during the survey is the highest count for this reach since the project started in 1993.

Reach 5: Seiad Bar river access to China Point river access.

A total of 140 redds were counted in this reach during the 2001 survey (Table 1; Figures 8 and 9). The 140 redds represent 6.4% of the total redd count for 2001. Redd density was 6.2 redds/rkm (Figure 3). Peak spawning (n=55) occurred during Week 3 of this survey. Reach 5 had the lowest redd count (n=140) of any reach sampled in 2001 (Table 1).

Reach 6: China Point river access to Indian Creek.

A total of 278 redds were counted in Reach 6 (Table 1; Figure 9). The 278 redds represent 12.8% of the total redd count for 2001. This represents a redd density of 14.6 redds/rkm (Figure 3) and the second highest redd count for this reach since 1993. Peak spawning (n=139) in Reach 6 occurred during Week 3 (Table 1).

Summary

Spawning was observed throughout the mainstem river from IGD to Indian Creek and was consistent with previous survey data in that spatial distribution of redds is highest in the upper mainstem (IGD to Ash Creek river access). The highest weekly redd count occurred during Week 3 (n=886). Overall, the 2001 redd survey yielded the second highest count during the period of record (1992-2001; Figure 5).

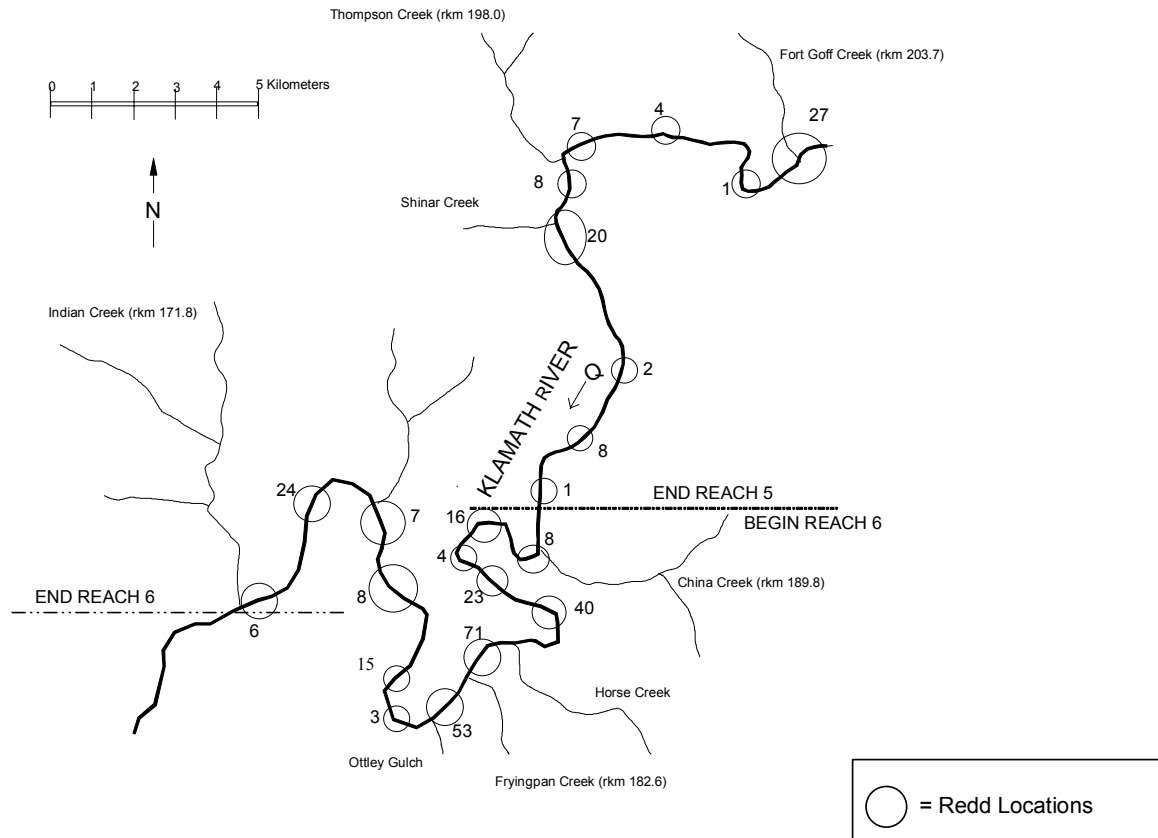

Figure 9. Redd distribution map for 2001, mainstem Klamath River, Fort Goff Creek to Indian Creek.

Redd counts: 10 km Sections

The 2001 redd counts were highest between IGD and Cape Horn Creek (Copco-Ager Bridge) with a redd density of 56.1 redds/rkm . The redd frequencies in this section increased from 24.2% to 60.9% during 1993 to 1999 (Table 2; Figure 10). In 2000 redd frequencies decreased to 37.5%. Redd frequencies for 2001 decreased to 25.8%. A very similar trend appears for the section between Cape Horn Creek and the Shasta River confluence (Table 2). Combined, these two upper mainstem sections account for 38.2% of the 2001 total redd count with the remaining 61.8% of the redds distributed between Shasta River and Indian Creek (Table 2). The lowest redd densities (4.3 redds/rkm) of any 10 rkm section occurred between Shinar Creek and China Creek.

Water Temperature

Mean daily water temperatures decreased from 15.5 to 6°C during this survey (October 15 and December 14, respectively). Water temperatures continued to decrease during these surveys even though IGD flows remained fairly stable 1,300 to 1,410 cfs (Figure 11).

Discharge

Discharges for the 2001 survey ranged from 1,300 to 1,410 cfs (Figure 10). While during the 1999 survey, mean daily discharges were some of the highest (1,360 to 1,820 cfs). With some of the lowest occurring during 1994 (906 to 962 cfs).

Water Clarity

Vertical Secchi disc readings ranged from 1.2 to 3.0 m during this survey compared to 1.2 to 2.0 m in 2000. The 1.2 m reading was observed on December 7 in Reach 6. The 3.0 m reading was observed on October 16 in Reach 1. Water clarity for this 2001 survey increased overall from the previous year survey. Visibility generally decreased with higher river discharge, cloud cover, and precipitation.

Table 2. Percent redd frequency by 10 rkm (approximate) section on the mainstem Klamath River, 1993 to 2001.

TRIBUTARY REACH (rkm)	REACH DISTANCE (rkm)	PERCENT FREQUENCY								
		1993	1994	1995	1996	1997	1998	1999	2000	2001
Iron Gate (306.1) to Cape Horn Ck (269.4)	10	24.2	38.9	39.1	40.9	45	55.1	60.9	37.5	25.8
Cape Horn Ck (269.4) to Shasta River (284.3)	12	2.1	11.1	15.6	10.6	14.2	16.1	11.7	12.5	12.4
Shasta River (284.3) to Humbug Ck (275.8)	9	2.7	1.1	1.9	0.8	1.1	3	3.3	5.8	3.6
Humbug Ck (275.8) to Vesa Ck (264.5)	11	5.5	2.2	1.1	1.1	1.8	1.6	2.9	3.5	2.8
Vesa Ck (264.5) to Little Humbug Ck (254.4)	10	5.8	6.9	5.2	4.8	3.3	3	2.9	7.5	10.3
Little Humbug Ck (254.4) to Kohl Ck (244.9)	10	7.9	3.4	4.9	3.3	4.3	3	0.9	5.1	7.2
Kohl Ck (244.9) to Kinsman Ck (234.2)	11	7.9	2.7	4.9	4.2	2.3	4.3	3.3	3.6	6.7
Kinsman Ck (234.2) to Kuntz Ck (224.4)	10	2.4	4.2	1.2	2.4	0.9	0.4	1.2	2.1	4.2
Kuntz Ck (224.4) to Walker Ck (214.4)	10	6.4	5.6	3.8	1.8	8.6	2.5	1.9	6.8	7.1
Walker Ck (214.4) to Portuguese Ck (205.3)	9	7.6	5.2	3.9	5.5	1	1	2.1	2.5	2.5
Portuguese Ck (205.3) to Shinar Ck (199.0)	10	1.2	3.9	2.2	3.1	1.4	1.4	1.6	1.3	3.2
Shinar Ck (199.0) to China Ck (189.8)	9	6.7	2.2	4.4	6	1.8	0.4	0.3	0.4	1.7
China Ck (189.8) to Ottley Gulch (181.1)	9	12.4	7.1	6	10.7	6.5	4.7	3.6	7.5	9.7
Ottley Gulch (181.1) to Indian Ck (171.3)	10	7.3	5.4	5.8	4.8	7.6	3.5	3	3.9	2.8

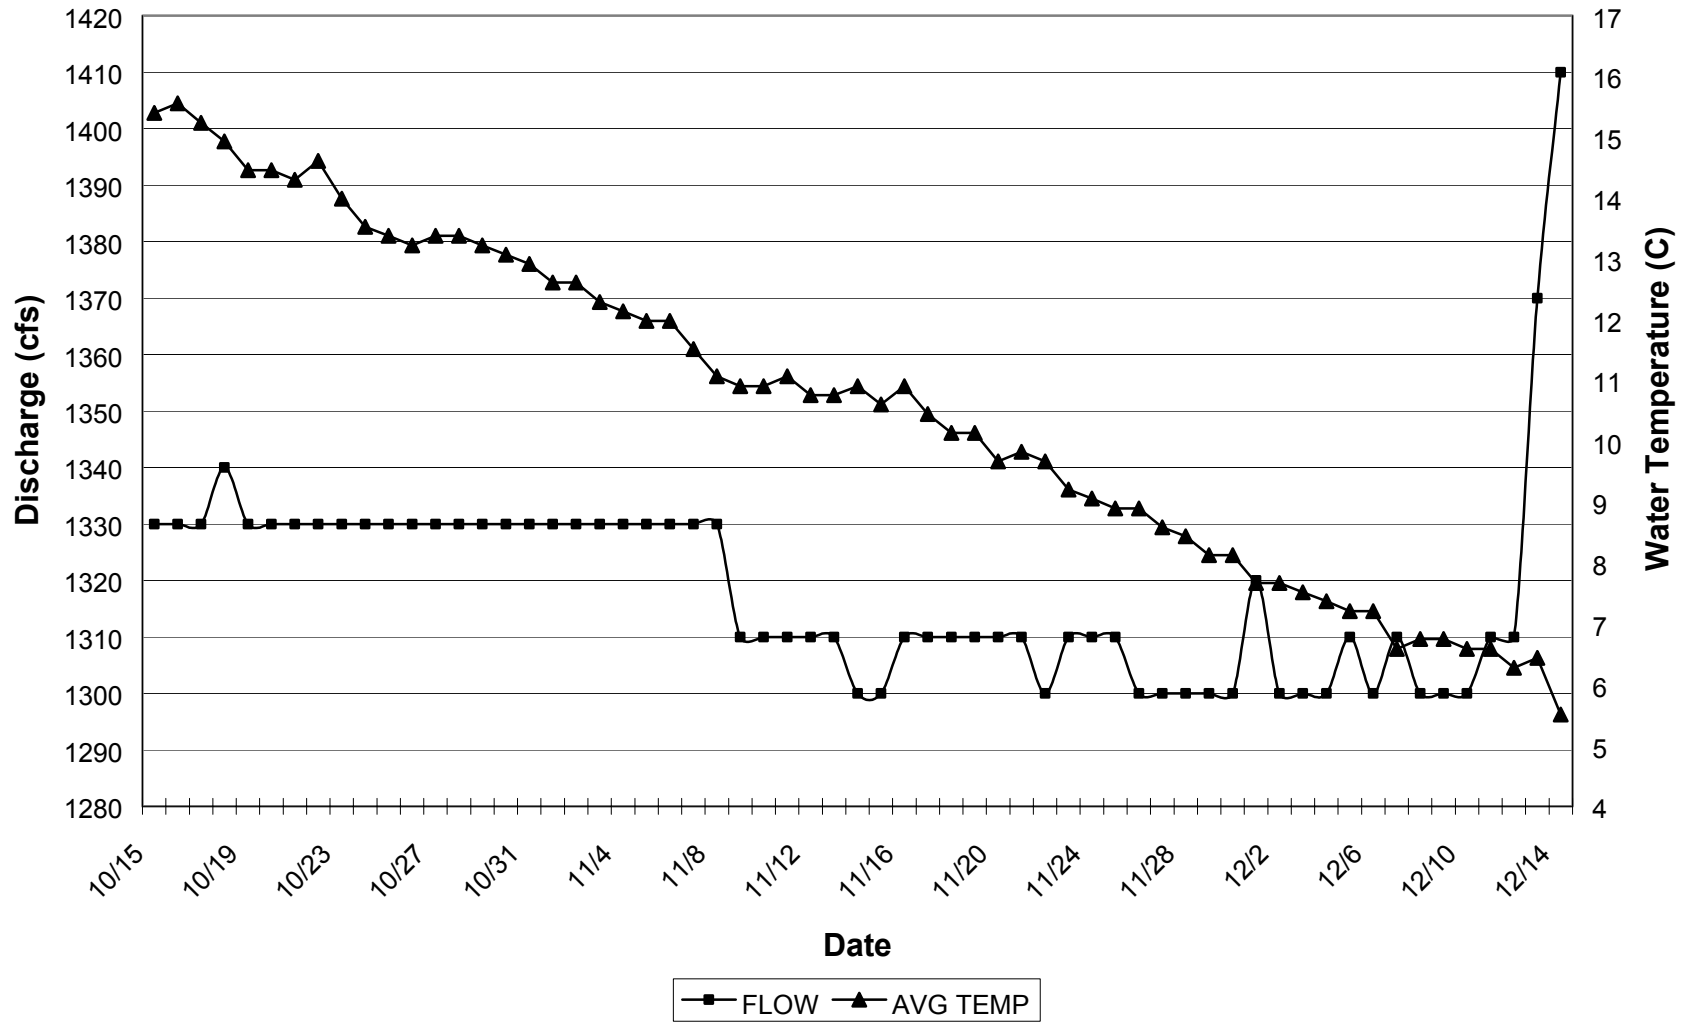

Figure 11. Water temperatures (°C) at rkm 300.4 and discharge (CFS) from Iron Gate Dam (October 15 to December 14, 2001).

Suction Dredge Mining

Recreational suction dredge mining was present throughout the survey from the HWY I-5 Bridge to Happy Camp. There was only one redd observed this year on suction dredge tailings. Studies have indicated that redds constructed on dredge tailings are more unstable in high flows than those on naturally deposited substrate (Harvey and Lisle 1999).

Adult Grilse Expansion

The CDFG estimated the natural fall chinook spawner escapement for the mainstem Klamath River for 2001 at 9,832 adults and 1,016 grilse (Table 3). The adult/grilse estimates are based on male to female ratio and jack percentages observed at upper Klamath River tributary weirs (Sinnen 2002).

Table 3. Natural fall chinook spawning escapement adult and grilse expansion, Klamath River, 2001 (Sinnen 2002).

Natural Spawning Area	Grilse	Adults	Totals
Salmon River Basin	743	2,607	3,350
Scott River Basin	744	5,398	6,142
Shasta River Basin	2,641	8,452	11,093
Bogus Creek Basin	648	11,927	12,575
Mainstem Klamath River IGH to Indian Creek	1,016	9,832	10,848
Total Natural Spawners	5,792	38,216	44,008

Based on spawning data from mainstem and tributary spawning surveys conducted by AFWO, USFS, CDFG, and Hoopa and Yurok tribes, the CDFG estimated that 133,167 adults spawned in-river or at hatcheries within the Klamath River Basin.

SUMMARY

The fall chinook redd count of 2,172 was the second highest number observed since the initiation of these surveys in 1993 when 330 redds were counted. The highest redd count was 3,240 redds observed in 1995. Since 1993, the tendency for chinook to spawn in the upper 10 rkm between IGD and Cape Horn Creek has increased to 60.9%, but declined in 2000 to 37.5%. In 2001 the tendency for chinook to spawn in this upper section declined once more to 25.8%.

Peak mainstem chinook spawning (40.8%) occurred during Week 3 (October 29 to November 2) in all reaches except for Reach 2. In Reach 2, peak spawning occurred during Week 2 (October 22 to October 26).

Water clarity during this years survey was some of the highest (1.2 to 3.0 m) observed when compared to past survey years.
