## Acknowledgements

The U.S. Fish and Wildlife Service acknowledges the following persons integral to the efforts of this project:

Bruce Halstead (Project Leader).
Mary Knapp (Assistant Project Leader).
George Guillen, for supervision and editing.
Tom Shaw, for supervision and editing.
John Lang, for supervision and editing.
Jim L. Craig, for supervision.
Bob Rohde, for supervising Karuk Tribal Fisheries staff.
Bill Pinnix, for supervision and editing.

We also appreciate the contributions of the following individuals who worked as crew members on this project:

Cornelius Hughey
Vic Sundberg
Brett Galyean
Mark Magneson

This project was done in cooperation with the following individuals of the Karuk Tribal Fisheries Office located in Orleans, CA:

Luana Hillman
Paul Kuska
Stephanie Myers
Troy Myers
Bill Tripp

Appreciation is also extended to the following volunteer staff who helped with various aspects of this report:

Tracy McCulloch
Mike Hastings
Special thanks to Al Andreoli, for allowing access through his property at the Trinity River trap site.

#### Abstract

Monitoring of juvenile salmonid emigration on the mainstem Klamath and Trinity rivers has been conducted by the Arcata Fish and Wildlife Office since 1988. Rotary screw traps have been utilized as monitoring devices on these rivers since 1989. This report describes monitoring conducted during 1997 through 2000. Catch data were used to calculate abundance indices for juvenile chinook salmon (Oncorhynchus tshawytscha), coho salmon (O. kisutch), and steelhead (O. mykiss). The age of outmigrants, length frequency distributions, development stages, migration rates, and hatchery contributions were also determined. River discharge and temperature data are also presented. Non-target species abundance and biological data are presented for sculpin (Cottus sp.), speckled dace (Rhinichthys osculus), Klamath smallscale sucker (Catostomus rimiculus), Pacific lamprey (Lampetra tridentata), American shad (Alosa sapidissima), green sturgeon (Acipenser medirostris), and threespine stickleback (Gasterosteus aculeatus). Catch data is also presented for less abundant species.

The Klamath River system is the second largest river system in California, draining an area of approximately 26,000 square kilometers $\left(\mathrm{km}^{2}\right)$ in California, and $14,400 \mathrm{~km}^{2}$ in Oregon. The Trinity River is the largest tributary to the Klamath River, draining approximately $7,690 \mathrm{~km}^{2}$ in California. Two dams, Iron Gate Dam on the Klamath River and Lewiston Dam on the Trinity River, are the upper limits of anadromous fish migration in the Basin. Two fish hatcheries, Iron Gate Hatchery (IGH) on the Klamath River and Trinity River Hatchery (TRH), were constructed to mitigate for losses of anadromous fish habitat upstream of Iron Gate and Lewiston dams.

The Klamath and Trinity rivers once supported large runs of chinook salmon (Oncorhynchus tshawytscha), coho salmon (O. kisutch) and steelhead trout (O. mykiss) which supported tribal, ocean troll and recreational fisheries. Declines in the Klamath Basin anadromous fish populations due to floods, water and land management, and fish harvest management (Klamath River Basin TF, 1991), led Congress to enact the Trinity River Basin Fish and Wildlife Restoration Act (PL 98-541) in 1984 and the Klamath River Basin Conservation Area Fishery Restoration Program (PL 99-552) in 1986. Both of these Acts directed the Secretary of the Interior to take actions necessary to restore the fishery resources of the Klamath Basin, primarily by addressing restoration of freshwater habitat.

Past fishery investigations in the Basin have focused primarily on adult returns, due to harvest allocation and escapement objectives. Data on adult returns is not adequate for monitoring restoration efforts in the basin because adult return data is affected by ocean mortality (both juveniles entering the ocean, and adult mortality), harvest at sea, and a number of other factors. The monitoring of emigrating juvenile salmonid populations in conjunction with habitat availability data and suitability studies may permit for the evaluation of restoration efforts because these studies focus on the juvenile phase of life which is most affected by instream conditions.

Intermittent juvenile salmonid investigations have been conducted in the Klamath River Basin by the Coastal California Fish and Wildlife Office (CCFWO) since 1981 (USFWS 1982, 1983). In 1988, a substantial monitoring effort was undertaken in both the mainstem Klamath and Trinity rivers utilizing frame nets, and in 1989, the utilization of rotary screw traps. The purpose of this project was to monitor the abundance, timing, hatchery contribution, and biological parameters of emigrating anadromous salmonids in the mainstem Klamath and Trinity Rivers. It is intended that this information will provide basic biological information that can be used by freshwater habitat managers and potentially fishery harvest managers.

## Methods

## Trapping Sites

During the spring months (Julian Weeks 1-39) of 1997 through 2000, Klamath River trapping was conducted at the Big Bar river access, located at river kilometer (rkm) 80 (16 rkms downstream of Orleans CA, and 10 rkm above the Trinity River confluence). The Big Bar trapping site was originally chosen in 1988. The site was selected because it allowed sampling of fish outmigrating from virtually the entire Klamath River Basin upstream of the Trinity River confluence, and the year-to-year channel configuration appeared to be consistent. The Big Bar site also allowed ready access by boat or vehicle and was not visible from Highway 96. During the spring and early fall (Julian Weeks 40-52) months of 1996 through 2000, Trinity River trapping was conducted at the Riverdale Campground (rkm 34) near Willow Creek (Figure 1). This location has been used since 1991 because the channel configuration is fairly consistent, it has private access, and the trap is not visible from Highway 96.

## Trap Design and Operation

Rotary screw traps with 2.44 m diameter cones were used (Figure 2). Traps were anchored with 0.64 cm diameter aircraft cable to large trees or a series of steel fence stakes upstream. One or two $0.1 \times 0.15 \times 6.0$ $\mathrm{m}(4 \mathrm{x} 6 \mathrm{x} \mathrm{x} 10$ ') beams were used to push the trap out from the bank and to compensate for changes in river stage and velocity. Cone revolutions were used to determine where and when the trap could be operated without inducing unnecessary risk to the trap. River conditions ultimately dictated when traps were deployed. An effort was made to place rotary traps in the river prior to the emigration of young-of-year (YOY) or age 0 chinook so that emigration patterns and the relative abundance of natural and hatchery chinook within all life history stages could be evaluated. The traps were fished on the edge of the thalweg during high river discharge, and incrementally moved back into the thalweg as river discharge decreased. When deployed, the bottom of the cone was generally $<1 \mathrm{~m}$ from the stream bottom. A sampling day was defined as the time period between the setting of the trap one day, and removal of captured fish approximately 24 hours later. This period encompassed all night hours, when the majority of juvenile salmonids emigrate. Trap checks usually occurred during late morning or early afternoon. During peak emigration periods, fish were removed from traps several times during the sampling period (the frequency dictated by water temperatures, fish numbers, and mortality rates).

Daily trap data were summarized by Julian week (JW; Table 1), with the first day of JW 1 commencing on the first day of the year. All JWs are seven days in length except the last JW of the year and the $9^{\text {th }}$ JW during leap years, which are both eight days in length.

Figure 1. Location of rotary screw trap sites on the Klamath and Trinity rivers in Northwestern CA.

Table 1. Julian week and corresponding first date.

## Water Flow and Temperature Measurements

Normal cone operating depth was 1.07 m . Daily velocity measurements were taken directly in front of the cone as follows: the submerged portion of the cone was divided into three cells (right, center, left); within each cell, velocity was measured at 0.2 and 0.8 of the cone operating depth for 60 seconds using a General Oceanics digital flowmeter (Model 2030) (General Oceanics, Inc. 1983). Mean water velocity (m/s) was calculated for each cell. Each cell area $\left(\mathrm{m}^{2}\right)$ was calculated, then multiplied by its corresponding mean water velocity $(\mathrm{m} / \mathrm{s})$. The values for each cell were summed, yielding an estimate of volume of river discharge sampled $\left(\mathrm{Q}_{\mathrm{s}}\right)$ in cubic meters per second $\left(\mathrm{m}^{3} / \mathrm{s}\right)$. Discharge data from U.S. Geological Survey Water Resource gauge stations at Orleans (\#11-523000 at rkm 95.2) on the Klamath River and at Hoopa (\#11-530000 at rkm 19.9) on the Trinity River were used as surrogate measures of mean daily river discharge $(\mathrm{Q})$ at the trap sites. It was assumed that there was no significant difference between river discharge at these gauging stations and the respective trap locations.

Water temperature data were collected using an Onset Stow Away Tidbit temperature logger attached to the outside bottom edge of each traps live box. Temperature was recorded every two hours for the entire sampling season. Mean daily river temperatures were calculated by averaging over 24-hour periods.

## Biological Sampling Procedures

All fish captured were anesthetized with tricaine methanesulfonate (MS-222) prior to processing. Up to 30 individuals of each species and developmental stage (parr, pre-smolt, smolt, etc.) were randomly subsampled (biosampled) from the daily catch. Biosampled salmonids were measured to the nearest mm fork length (FL), weighed by volumetric displacement, and examined for developmental stage, fin clips, and physical irregularities. All captured salmonids that were not biosampled were tallied by species, development stage and/or age and examined for fin clips.

Fish other than chinook, coho, or steelhead were considered non-target species. Non-target fishes captured were identified to species (or genus in some cases), enumerated, and up to 30 specimens were measured to FL. Total length (TL) was measured on species without a forked caudal fin. All anesthetized fish not retained were allowed to resuscitate in buckets of ambient river water before being released downstream of the trap. NovAqua ${ }^{\circledR}$ water conditioner was added to recovery buckets to help protect fish during handling, minimize infection, reduce stress and aid in recovery. Adult salmonids were not anesthetized. Fork lengths of adult salmonids were approximated before release. Any salmonid mortality in the live box was checked for a fin clip and, if included in the subsample, measured (FL). If a salmonid escaped during netting or handling before it could be identified to species or checked for a hatchery mark (i.e. fin or maxillary clip), it was counted in the sample tally as an "unknown". Based on the probability of occurrence, unknown fish were redistributed into the most likely marked or unmarked species categories.

When present, daily subsamples of marked hatchery chinook were collected. A missing adipose fin (Ad-clip) was the external marker depicting fish with a coded wire tag (CWT) embedded in the snout. A maximum of five hatchery chinook were collected daily. Ad-clipped fish were sacrificed for subsequent CWT retrieval. Collected fish were stored in a freezer until time of dissection. Occasionally, Ad-clipped fish were also collected for disease sampling, after which the CWT's were removed.

Juvenile chinook were classified as Age 0 (young of year) or Age 1, based on size and date of capture. Coho were classified as either Age 0 or Age 1; the latter of which were much larger in size, silvery, and lacked distinct parr marks. Steelhead were also classified by age classes based on size and scale analysis. Scale samples were collected from a subsample of chinook, coho, and steelhead for age analysis. Fish were assigned an age based on the number of annuli (overwinter period) present. A fish with one annuli was classified as a Age 1, two annuli designated as Age 2, etc.

Age 0 chinook and coho captured in 1997 were produced from adult spawners in 1996 and were therefore considered 1996 brood year (BY), while Age 1 chinook and coho were BY 1995 fish. Age 0 steelhead captured in 1997 were considered BY 1997, while Age 1 and Age 2 steelhead were considered BY 1996 and BY 1995 respectively.

## Hatchery and Natural Stocks Estimate

Captured chinook and coho were later categorized as being either of hatchery or natural origin, based on hatchery marks and hatchery release data provided by TRH and IGH. The California Department of Fish and Game (CDFG) coded wire tagged and Ad-clipped natural chinook from the upper Trinity River as part of their natural stocks assessment program. Natural fish are defined as the progeny of river or tributary spawning adults regardless of parental genetics. Hatchery release strategies for chinook consist of fingerling releases in the spring and "yearling" releases in the fall. These two distinct release periods prompted the division of the trapping season into spring and fall monitoring periods. The spring monitoring period was designated as JW 1 through 39 and the fall period 40 through 52. Hatchery coho and steelhead were released as Age 1 fish in the spring.

## Chinook

All Ad-clipped fish collected were passed through a magnetic field detector manufactured by Northwest Marine Technology to determine the presence or absence of a CWT. The snout of each fish that registered positive for a tag was dissected until the CWT was recovered. Each fish registering negative for a tag had its head dissolved in a solution of potassium hydroxide. A magnet was then stirred through the resultant slurry. If the tag was not recovered, the fish was considered an Ad-clipped fish that had shed its tag (No-Tag). Recovered tags were decoded using a dissection microscope. CWT recoveries were summed by specific CWT code for each JW.

The number of CWT fish captured for each code was estimated by multiplying the number of CWT's recovered by an expansion factor (E) which accounted for subsampling of Ad-clipped fish, CWT's that were lost during dissection, and unreadable tags. The expansion factor (E) was calculated using the formula:

```
E =(C/MS)(Ad/H)(T/TR)
```

| Where, | $\mathrm{C}=$ | Total \# of chinook captured, |
| :--- | :--- | :--- |
| $\mathrm{MS}=$ | Number of fish examined for Ad-clips, |  |
| $\mathrm{Ad}=$ | Number of Ad-clipped fish observed, |  |
| $\mathrm{H}=$ | Number of Ad-clipped fish collected, |  |
| $\mathrm{T}=$ | Number of collected Ad-clipped fish containing a CWT, |  |
| $\mathrm{TR}=$ | Total number of CWT's recovered and decoded after processing. |  |

To account for unmarked hatchery fish over a JW, the expanded estimates for each CWT code were multiplied by a production multiplier (PM) specific to each CWT code. Each PM was calculated from hatchery release data (Pacific States Marine Fisheries Commission, 1997,1998,1999, 2000), using the following formula:

```
PM = # Tagged + # Poor Tagged + # Unmarked
    # Tagged
Where: # Tagged = The actual number of Ad-clipped fish released with a CWT,
    # Poor Tagged = The number of Ad-clipped fish that were tagged and shed the tag
        (No-Tags),
    # Unmarked = The number of unmarked fish in a release group.
```

The estimated contribution of hatchery fish attributable to a specific CWT code for a given JW, was calculated by the following formula:

$$
\text { \# Hatchery }{ }_{\text {code } \mathrm{i}}=\left(\# \text { recovered } \mathrm{d}_{\text {code }} \mathrm{i}\right) *\left(\mathrm{E}_{\text {code }} \mathrm{i}\right) *\left(\mathrm{PM}_{\text {code }} \mathrm{i}\right)
$$

The total weekly estimated hatchery contribution to the catch was the sum of all estimated hatchery fish attributable to CWT codes. The weekly contribution of naturally produced chinook to the catch was estimated by subtracting the estimated hatchery contribution from the total weekly catch. Occasionally, the daily estimated hatchery contribution exceeded the total daily catch. In such instances the estimated hatchery contribution was limited to the actual daily catch.

Towards the end of each emigration period, due to relatively few fish passing by the trap, it is possible that we captured juveniles of hatchery origin not represented by Ad-clipped fish. If no hatchery fish captured within a given time period were marked, the hatchery contribution for that period could not be differentiated from the natural component. Thus, all fish captured during that period were considered of natural origin. The hatchery and natural stock estimates assume no differential mortality between tagged and untagged fish of the same release group, equal vulnerability to capture and accurate estimates of the numbers of marked, unmarked and poor tagged fish released from the hatchery. The estimate does not account for Ad-clipped or non-Ad-clipped hatchery fish removed from the river upstream.

Coho

All hatchery coho released in 1997-2000, were marked with a maxillary clip (TRH coho received a right maxillary clip and IGH coho received a left maxillary clip). The weekly contribution of naturally produced coho to the catch was estimated by subtracting the actual hatchery contribution (marked fish) from the total weekly catch.

Steelhead

Hatchery steelhead released in 1997-2000 were marked with an adipose fin clip. Analysis of scale samples taken over the sampling season provided length to age relationships.

## Abundance Index

Catch effort data were recorded and evaluated for each sample day. Trends in emigration were analyzed on a JW basis using daily abundance indices, adjusting for days not sampled (occasionally woody debris or an accumulation of aquatic vegetation would cause the cone to cease rotating). Daily abundance indices (Index $\mathrm{X}_{\mathrm{d}}$ ) for each species and development stage were calculated by the following equation:

$$
\begin{aligned}
& \text { Index }=\text { Catch }_{\mathrm{d}} /\left(\mathrm{Q}_{\mathrm{s}} / \mathrm{Q}\right) . \\
& \text { Where: } \quad \begin{array}{l}
\text { Catch } \\
\\
\\
\\
\\
\mathrm{Q}_{\mathrm{s}}=\text { volume of water sampled }(\mathrm{cfs}) \\
\mathrm{Q}=\text { mean daily river discharge }(\mathrm{cfs})
\end{array}
\end{aligned}
$$

Weekly abundance indices were calculated for each JW using the following equation:

$$
\text { Index }_{\mathrm{JWi}}=\Sigma \operatorname{Index}_{\mathrm{d}}\left(\# \text { days in } \mathrm{JW}_{\mathrm{i}} / \# \text { days sampled during } \mathrm{JW}_{\mathrm{i}}\right)
$$

Abundance indices were also calculated for the more abundant non-target species in the same manner as for salmonids.

The usefulness of this index as an estimator of abundance is contingent upon the assumptions that catch rates are directly proportional to the percentage of river flow sampled and that individuals from a given species are equally susceptible to capture. The abundance index is not intended to represent a population estimate it is used to compare relative abundance between weeks during the trapping season, between trapping seasons, and between years.

## Migration Rate

Initial migration rates for hatchery chinook and coho were estimated by dividing the distance (rkm) traveled by the number of days elapsed between the initial release date and initial capture date for specific CWT codes or marked fish. Mean migration rates were calculated for each CWT group throughout the trapping period. Because IGH released chinook over a 3-day period (June 3-5) during the spring of 1997, the median date of June 4 was used as the initial release date when calculating mean migration rates. Due to a prolonged release period (March 18 to March 31), mean migration rates were not calculated for TRH chinook. Naturally produced chinook tagged by CDFG on the Trinity River were tagged in early spring of 1997, before initiation of migration, so migration rates for these CWT groups were not calculated.

Daily migration rates were weighted by the proportion of river flow sampled to reflect the untrapped fish passing through the sampling area. A mean migration rate per CWT code or marked fish was calculated by the following formula with the first $10 \%$ and last $10 \%$ of each group excluded:

Where \# = Daily expanded $\mathrm{CWT}_{\mathrm{i}}$ code or fin clip counts, $\mathrm{rkm} / \mathrm{d}=$ distance traveled divided by number of days taken to reach trap after initial release, $\mathrm{Q}=$ mean daily volume of river discharge, $\mathrm{Q}_{\mathrm{s}}=$ volume of river discharge sampled.

The 10 through 90 percent capture dates were used to calculate the migration rate of the majority of each specific CWT or mark group. When less than ten tags of any specific release group were recovered all tags were used. Ad-clipped chinook not collected (i.e.; released at time of capture) were included in migration rate calculations using tag allocation procedures previously described in the hatchery and natural stocks estimation section of this report (page 8).

Chinook monitoring on the mainstem Klamath River at Big Bar

Juvenile salmonid monitoring on the Klamath River at Big Bar occurred for 126, 97, 115 and 87 days respectively in 1997, 1998, 1999 and 2000, coinciding with trap deployment in March or April and ending in July or August. End dates are in part due to the water-year type, timing and duration of sustained high water temperatures, catch levels and the accumulation rate of algal drift. The Big Bar trap (BBT) effectively fished 82, 87, 91 and 89 percent of the total days possible (start date to end date) respectively, in 1997, 1998, 1999 and 2000 (Table 2).

Table 2. Period and duration of Spring monitoring, trapping rate and date of peak daily average water temperature at the BBT, 1997-2000.

|  |  |  |  |  | Peak daily <br> average water <br> temperature ${ }^{\circ} \mathrm{C}$ | Days <br> occurred |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Year | Start-end dates | Trapped | Days <br> possible | rate |  |  |

Annually, Iron Gate Hatchery (IGH) released between 4.7 and 5.6 million chinook fingerlings in June.
Releases include AD-clipped CWT groups representing between 3.6 and 4.3 percent of a given brood-years fingerling release total. There are 225 river kilometers (rkm) between IGH and the BBT. The time between release and first capture of an Ad-clipped fingerling at the BBT ranged from 4 days in 2000 to 16 days in 1999. The 4 day travel time in 2000 represents an initial emigration rate of $56.3 \mathrm{rkm} /$ day. The mean emigration rate is more representational of the total release rate. Mean emigration rates for IGH fingerlings and ranged between 7.4 and $11.8 \mathrm{rkm} /$ day (Table 3).

Table 3. Iron Gate Hatchery fall-run fingerling releases and recoveries at the BBT, 1997-2000.

| IGH Age 0 Fall Chinook Releases |  |  |  | Migration rates |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 2000 | 5,028,070 | 3.6\% | 6/09-6/10 | 6/13/00 | 4 | 56.3 | 8.12 | 205 |

## Chinook Catch Totals

For spring monitoring 1997 through 2000, the number of Age 0 chinook captured at the BBT ranged from 11,153 to 27,067 fish. Catch-per-unit effort totals ranged from 120 in 2000, to 279 in 1998. The overall chinook Age 0 catch in 1998 was the largest since initiating downstream migrant trapping at Big Bar in 1988. Hatchery percentage in trap catches for 1997-2000, ranged from $44 \%$ in 2000 to $83 \%$ in 1997 (Table 4).

Table 4. BBT hatchery and natural Age 0 chinook catch totals, catch-per-unit effort (CPUE), and hatchery percentages, Spring monitoring, 1997-2000.

| Spring <br> Monitoring | $\begin{gathered} \text { Days } \\ \text { Fished } \end{gathered}$ | Age 0 Chinook |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Hatchery | Natural | Total | CPUE | \% Hatchery |
| 1997 | 126 | 15,700 | 3,108 | 18,808 | 149 | 83\% |
| 1998 | 97 | 14,359 | 12,708 | 27,067 | 279 | 53\% |
| 1999 | 118 | 10,935 | 7,877 | 18,812 | 159 | 58\% |
| 2000 | 93 | 4,962 | 6,191 | 11,153 | 120 | 44\% |
| 97-00 Totals | 434 | 45,956 | 29,884 | 75,840 | 707 | 61\% |
| 97-00 Avg | 109 | 11,489 | 7,471 | 18,960 | 177 |  |

As in past years (USFWS, 1991, 1992a, 1992b, 1994), a few Age 1 "yearling" chinook are captured each spring. Ad-clipped yearlings are released from Iron Gate Hatchery each October. A total of 28 non-Adclipped chinook and 3 Ad-clipped yearlings were captured in the four spring trapping periods.

## Chinook Catches and Fork Lengths

Spring 1997: Fork lengths from 1,691 chinook ( $9 \%$ of the total catch) were measured. Mean fork lengths of Age 1 chinook range from 116 mm to $140 \mathrm{~mm}(\mathrm{n}=6)$ and were captured in 3 consecutive weeks (JW 19-21) in May. Initial catches of Age 0 chinook occurred in JW $15(0=39, \mathrm{sd}=1.0, \mathrm{n}=3)$ (Figure 3). Mean fork lengths increased steadily through JW $24(0=104, \mathrm{sd}=12.4, \mathrm{n}=199)$. In JW 25 hatchery fish were first observed and comprised $59 \%$ of the catch that week. CPUE increased significantly from 244 fish in JW 25 to a peak of 1,033 fish in JW 27 before dropping off significantly. Upon the arrival of hatchery fish, mean weekly fork lengths decreased from a mean of $104 \mathrm{~mm}(\mathrm{sd}=12.37, \mathrm{n}=199)$ to a mean of $88 \mathrm{~mm}(\mathrm{sd}=7.5, \mathrm{n}=246)$. Trapping became intermittent after JW 32. The mean fork length at that time was $102 \mathrm{~mm}(\mathrm{sd}=12.6, \mathrm{n}=33)$ (Appendix 25).

Spring 1998: Fork lengths from 1,650 chinook ( $6.1 \%$ of the total catch) were measured. Mean fork lengths of Age 1 chinook range from 128 mm to $193 \mathrm{~mm}(\mathrm{n}=10)$ and were captured from the beginning of trapping in April through mid-June (Figure 3). Initial catches of Age 0 chinook occurred in JW $18(0=73, \mathrm{sd}=30.4$, $\mathrm{n}=5)$ (Figure 3). Mean fork lengths increased steadily through JW $23(0=101, \mathrm{sd}=9.7, \mathrm{n}=212)$. In JW 24 hatchery fish were first observed and comprised $2 \%$ of the catch that week. CPUE increased significantly from 145 fish in JW 24 to a peak of 900 in JW 25. The CPUE remained high, greater than 200 fish, before dropping off significantly during JW 30. Upon arrival of hatchery fish, mean weekly fork lengths decreased from a mean of 101 mm ( $\mathrm{sd}=9.7, \mathrm{n}=212$ ) to a mean of $91 \mathrm{~mm}(, \mathrm{sd}=7.0, \mathrm{n}=210)$. Trapping concluded on JW 31, with a mean weekly fork length of 93 mm ( $\mathrm{sd}=9.1, \mathrm{n}=125$ ) (Appendix 27).

Spring 1999: Fork lengths from 1,577 chinook ( $8.4 \%$ of the total catch) were measured during spring 1999 monitoring. Age 1chinook were captured in JW $17(0=152, \mathrm{n}=1)$ and again in JW $22(0=134, \mathrm{sd}=8.5, \mathrm{n}=2)$ (Figure 3). Initial catches of Age 0 chinook occurred in JW $15(0=38, \mathrm{sd}=2.1, \mathrm{n}=2)$ (Figure 3). Mean fork lengths increased steadily through JW $23(0=61, \mathrm{sd}=14.2$, $\mathrm{n}=12)$. In JW 27 hatchery fish were first observed and comprised $19 \%$ of the catch that week. CPUE steadily increased from 2 fish in JW 24 to a peak of 1,729 fish in JW 28 before dropping of significantly. Upon the arrival of hatchery fish, mean weekly fork lengths decreased from a mean of $97 \mathrm{~mm}(\mathrm{sd}=9.0, \mathrm{n}=200)$ to a mean of $92 \mathrm{~mm}(\mathrm{sd}=6.7, \mathrm{n}=180)$. Trapping concluded on JW 32, with a mean weekly fork length of $94 \mathrm{~mm}(\mathrm{sd}=11.2, \mathrm{n}=49)$ (Appendix 29).

Figure 3. Chinook Age 0 and Age 1 mean fork lengths (mm) by Julian week on the BBT, 1997-2000.
(+/- 1 standard error, sample size)

Spring 2000: Fork lengths from 904 chinook ( $8.2 \%$ of the total catch) were measured during spring 2000 monitoring. Mean fork lengths of Age 1 chinook, captured between JW 17 and JW 22, ranged from 120$182 \mathrm{~mm}(\mathrm{n}=8)$ (Figure 3). Initial catches of Age 0 chinook occurred in JW $14(0=38, \mathrm{sd}=3.5, \mathrm{n}=2)$. Mean fork lengths increased steadily through JW $21(0=98, \mathrm{sd}=11.3, \mathrm{n}=165)$ (Figure 3). In JW 22 hatchery fish were first observed and comprised $17 \%$ of the catch that week. CPUE increased from 37 fish in JW 22 to a peak of 762 fish in JW 26 before dropping off significantly. Upon arrival of hatchery fish, mean weekly fork lengths increased from a mean of $69 \mathrm{~mm}(\mathrm{sd}=10.8, \mathrm{n}=16)$ to a mean of $79 \mathrm{~mm}(\mathrm{sd}=19.5, \mathrm{n}=32)$. Trapping became intermittent after JW 27. The mean fork length at that time was $87 \mathrm{~mm}(\mathrm{sd}=12.5, \mathrm{n}=6)$ (Appendix 31).

Chinook Abundance Indexes and Hatchery Contributions by Year
Spring 1997: Monitoring at the BBT began in late March, with very few natural Age 0 chinook were captured before the beginning of June. Catches increased weekly throughout the month of June, with the peak weekly catch occurring in the last week of June (JW 26). Hatchery Age 0 chinook contributions began during JW 25 and peaked in JW 27 (Figure 4). Spring monitoring at the BBT ended in late August due to low trap catches and large algae loads. The 1997 BBT abundance index total was 546,736.

Spring 1998: Monitoring at the BBT began in late April, with very few natural Age 0 chinook being captured before the beginning of June. Catches increased weekly throughout the month of June, with the peak weekly catch occurring in the second week of July (JW 28). Hatchery Age 0 chinook contributions began during JW 24 and peaked in JW 25 (Figure 4). Spring monitoring at the BBT ended in mid August due to low trap catches and large algae loads. The 1998 BBT abundance index total was 1,914,406.

Spring 1999: Monitoring at the BBT began in early April, with very few natural Age 0 chinook being captured before the middle of June. Catches increased weekly throughout the month of June, with the peak weekly catch occurring in the second week of July (JW 28). Hatchery Age 0 chinook contributions began during JW 27 and peaked in JW 28 (Figure 4). Spring monitoring at the BBT ended in early August due to low trap catches and large algae loads. The 1999 BBT abundance index total was 798,674.

Spring 2000: Monitoring at the BBT began in early April, with few natural Age 0 chinook being captured before early June. Catches increased weekly throughout the month of June, with the peak weekly catch occurring in the third week in June (JW 25). Hatchery Age 0 chinook contributions began during JW 22 and peaked in JW 26 (Figure 4). Spring monitoring at the BBT ended in early Mid July due to low trap catches and large algae loads. The 2000 BBT abundance index total was 511,798.

Figure 4. Weekly abundance index totals for natural and hatchery chinook at the BBT, 1997-2000

## Emigration Timing

A consistent feature in all four spring monitoring periods 1997-2000, is that few natural Age 0 chinook were captured prior to the beginning of June (JW 23). Natural chinook emigration occurred earlier in 1997 and 2000 compared to 1998 and 1999, and corresponds to increased water temperatures occurring earlier in the spring (Figure 5). Water temperatures reached $15^{\circ} \mathrm{C}$ in early May 1997, mid-May in 2000, late May in 1998 and early June in 1999 (Figure 6). Sustained high water temperatures occurred in both 1997 and 2000, leading to stress related fish kills. In 2000, dead fish were observed in late June and early July. CDFG estimated fish deaths in the tens of thousands as a conservative estimate, and that the true number could be as many as 100,000 to 300,000 fish (chinook, Age 0, and Age 0, Age 1 and Age 2 steelhead) that died in the mainstem Klamath River (CDFG 2000). A similar fish kill occurred in 1997, but later in the summer (August) and included a wider range of non-salmonid species. Both the 1997 and 2000 fish kills occurred following a period of sustained high air temperatures with resultant increases in mainstem water temperatures. Two pathogens endemic to the Klamath Basin: Ceratomyxa shasta (ceratomyxosis) and Flavobacterium columnare (columnaris) are stress triggered infections and likely the direct cause of death, although low dissolved oxygen levels are also suspected in 1997.

Figure 5. Emigration timing of natural (A) and hatchery Chinook (B) captured at the BBT, Spring 1997-2000.

Figure 6. Mean daily flow (cfs) at Orleans and mean daily river temperature $\left({ }^{\circ} \mathrm{C}\right)$ at the BBT, 1997-2000.

## Chinook Monitoring on the Mainstem Trinity River at Willow Creek:

Juvenile salmonid monitoring on the Trinity River at Willow Creek occurred for 231, 206, 189 and 143 days respectively in 1997, 1998, 1999 and 2000. Trapping began prior to significant natural fall-run chinook outmigration in late March or April and continued through late September or October (Table 5). Because the Trinity River Hatchery (TRH) conducts both spring (fingerling) and fall (yearling) releases, trapping at Willow Creek trap (WCT) was divided into spring and fall monitoring periods. Trapping was concluded when funding was exhausted or when fall storms made trapping difficult. Late summer algae blooms were not as problematic on the Trinity River as on the Klamath River, therefore trapping operations could continue on the Trinity throughout the summer and into the fall.

The Willow Creek Trap effectively fished 90, 94, 96 and 99 percent respectively, of the total possible trap days in 1997, 1998, 1999 and 2000 monitoring period (Table 5). Consistent daily data collection was disrupted (flawed set) intermittently by large woody debris and mechanical difficulties.

Table 5. Period and duration of Spring and Fall monitoring, trapping rate and date of peak daily average water temperature at the WCT, 1997-2000.

| Year | Start-end dates | $\begin{gathered} \text { Days } \\ \text { Trapped } \\ \hline \end{gathered}$ | Days possible | Trapping <br> rate | Peak daily average water temperature oC | Date occurred |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1997 | March 26 -Dec 07 | 231 | 257 | 90\% | 23.9 | Aug 8 |
| 1998 | April 16 - Nov 20 | 206 | 220 | 94\% | 24.6 | Aug 14 |
| 1999 | March 18 - August 30 | 189 | 197 | 96\% | 22.3 | July 13 |
| 2000 | May 16 - Oct 06 | 143 | 144 | 99\% | 23.9 | Aug 2 |

Winter and spring storms produced high flow events ranging from $31,000 \mathrm{cfs}$ to $101,000 \mathrm{cfs}$ during the 19972000 trapping period. In 1997 a peak flow of $101,000 \mathrm{cfs}$ was recorded at Hoopa on January $1^{\text {st }}$. Intermittent storms in 1998, produced two high flow events, 57,000 cfs on January $17^{\text {th }}$ and 66,800 cfs on March $23^{\text {rd }}$. In 1999 a peak flow of $31,000 \mathrm{cfs}$ was recorded at Hoopa on March $1^{\text {st }}$. In 2000 a peak flow of 37,000 cfs was recorded on February $15^{\text {th }}$.

Trinity River Hatchery (TRH) released 3.1, 3.7, 3.2 and 2.9 million chinook fingerlings in spring of 1997, 1998, 1999 and 2000 respectively (Table 6). Releases included adipose fin clipped (AD-clip) CWT groups, representing 8.9 to 21.1 percent of brood-year fingerling releases. Fingerlings were released at Hardhat and Sky Ranch which are 134 and 148 river kilometers ,respectfully, upstream of the WCT. Ad-clipped TRH releases were first captured at the WCT 3 to 129 days after release, representing mean outmigration rates from the upper Trinity River of 10.8 to 1.4 rkm 's per day.

TRH released 1.3, 1.3, 1.4, and 1.2 million chinook fingerlings in fall of 1997, 1998, 1999, and 2000 respectively (Table 6). Releases included AD-clip CWT groups, representing 12.0 to 35.1 percent of broodyear fingerlings releases. Fingerlings were released at Hardhat and Sky Ranch which are 134 and 148 river kilometers, respectfully, upstream of the WCT. Ad-clipped TRH releases were first captured at the WCT 3 to 4 days after release, representing mean outmigration rates from the upper Trinity River of 6.9 to 18.2 rkm's per day.

Table 6. Trinity River Hatchery fingerling releases and recoveries at the WCT, 1997-2000.

|  | Fall | 863,988 | 34.7\% | 10/2-10/15 | No data collected |  |  |  |  |

## Spring Monitoring Catch Totals

Spring monitoring on the WCT was conduced from 137 to 189 days during the 1997-2000 trapping period (Table 7). During the spring season monitoring, the number of Age 0 chinook captured ranged from 23,443 to 47,417 fish. Catches were predominately Age 0 with few yearling fish captured. The two years that Age 1 chinook were captured (1997 and 2000) they comprised only .02 and .004 percent respectively of the total spring chinook catch (Appendix 1 and 10). Hatchery Age 1 chinook released in the fall and captured the following spring also occurred in past monitoring (USFWS 1991, 1992a, 1992b, 1994).

Table 7. Chinook catch totals at the WCT, Spring monitoring, 1997-2000.

| Spring <br> monitoring | Days <br> trapped | Age 0 Chinook |  |  |  |  |
| :---: | :---: | ---: | ---: | ---: | ---: | ---: |
|  |  | Natural | Total | CPUE | $\%$ Hatchery |  |
| 1997 |  | 17,847 | 10,184 | 28,031 | 164 | $64 \%$ |
| 1998 |  | 28,824 | 18,436 | 47,260 | 301 | $61 \%$ |
| 1999 |  | 10749 | 14920 | 25,669 | 136 | $42 \%$ |
| 2000 |  | 10263 | 13042 | 23,305 | 170 | $44 \%$ |
| $97-00$ Totals | 654 | 67,683 | 56,582 | 124,265 | 190 | $54 \%$ |
| $97-00$ Avg | 164 | 16,921 | 14,146 | 31,066 | 193 | $53 \%$ |

## Fall Monitoring Catch Totals

Fall Monitoring on the WCT was conducted from 0 to 60 days during the 1997-2000 trapping period.
(Table 8). During fall season monitoring the number of Age 0 chinook captured ranged from160 to 51479. Catches were all Age 0 chinook with hatchery fish making up the majority of the catch for all years (Table 8).

Table 8. Chinook catch totals at the WCT, Fall monitoring, 1997-2000.

| Fall <br> monitoring | Days <br> trapped | Age 0 Chinook |  |  |  |  |
| :---: | :---: | ---: | ---: | ---: | ---: | ---: |
|  |  | Natural | Total | CPUE | \% Hatchery |  |
| 1997 |  | 11,263 | 1,995 | 13,318 | 222 | $85 \%$ |
| 1998 |  | 28,567 | 22,863 | 51,479 | 1051 | $55 \%$ |
| 1999 |  |  |  |  |  |  |
| 2000 |  | 98 | 56 | 160 | 27 | $61 \%$ |
| $97-00$ Totals | 115 | 39,928 | 24,914 | 64,842 | 564 | $62 \%$ |
| $97-00$ Avg | 29 | 13,309 | 8,305 | 21,652 | 433 | $67 \%$ |

Chinook Catches and Fork lengths

Spring and Fall 1997: Fork lengths from 4,538 chinook ( $10.7 \%$ of the total catch) were measured (Appendix 33). Mean fork lengths of Age 1 chinook range from 115 mm to $145 \mathrm{~mm}(\mathrm{n}=4)$ and were captured between JW 15 and JW 24. Initial catches of Age 0 chinook occurred in JW $13(0=38 \mathrm{~mm}, \mathrm{sd}=1.5, \mathrm{n}=14)$ (Figure 7). Mean weekly fork lengths increased steadily throughout JW $23(0=98 \mathrm{~mm}, \mathrm{sd}=12.4, \mathrm{n}=113)$. In JW 24 hatchery fish were first observed and comprised $68 \%$ of the catch that week. CPUE increased from 33 fish in JW 23 to a peak of 966 fish in JW 28 before dropping off. Upon the arrival of hatchery fish, mean weekly fork lengths increased slightly from $98 \mathrm{~mm}(\mathrm{sd}=12.4, \mathrm{n}=113)$ to $100 \mathrm{~mm}(\mathrm{sd}=10.1, \mathrm{n}=208)$. Spring trapping concluded on JW 39 with a mean fork length of 106 mm ( $\mathrm{sd}=9.9, \mathrm{n}=179$ ). Fall trapping began on JW 40 with significant increases in hatchery and natural Age 0 chinook catches. Mean weekly fork lengths also increased from 106 mm ( $\mathrm{sd}=9.9$, $\mathrm{n}=179)$ to $119 \mathrm{~mm}(\mathrm{sd}=19.4, \mathrm{n}=195)$. Catch for both hatchery and natural Age 0 chinook peaked during JW 41. The mean fork length at that time was $135 \mathrm{~mm}(\mathrm{sd}=13.6, \mathrm{n}=210)$. Trapping concluded on JW 49 with a mean fork length of $133 \mathrm{~mm}(\mathrm{sd}=14.8, \mathrm{n}=8)$.

Spring and Fall 1998: Fork lengths from 4,347 chinook ( $5.4 \%$ of the total catch) were measured (Appendix 35). No Age 1 chinook were captured in 1998. Initial catches of Age 0 chinook occurred in JW $16(0=38 \mathrm{~mm}$, $\mathrm{sd}=1.7, \mathrm{n}=19$ ). Mean weekly fork lengths increased steadily throughout JW $24(0=78 \mathrm{~mm}, \mathrm{sd}=19.9, \mathrm{n}=29)$. In JW 25 hatchery fish were first observed and comprised $17 \%$ of the catch that week. CPUE increased from 4 fish in JW 24 to a peak of 1,277 fish in JW 31. Upon arrival of hatchery fish, mean weekly fork lengths increased from $78 \mathrm{~mm}(\mathrm{sd}=19.9, \mathrm{n}=29)$ to $87 \mathrm{~mm}(\mathrm{sd}=13.6, \mathrm{n}=91)$. Spring trapping concluded on JW 39 with a mean fork length of $105 \mathrm{~mm}(\mathrm{sd}=6.4, \mathrm{n}=210)$. Fall trapping began on JW 40 with significant increases in hatchery and natural Age 0 chinook catches. Mean weekly fork lengths also increased from 105 mm ( $\mathrm{sd}=6.4$, $\mathrm{n}=210)$ to $114 \mathrm{~mm}(\mathrm{sd}=13.1, \mathrm{n}=210)$. Catch for both hatchery and natural Age 0 chinook peaked during JW 41. The mean fork length at that time was $125 \mathrm{~mm}(\mathrm{sd}=11.9, \mathrm{n}=210)$. Trapping concluded on JW 47 with a mean fork length of $121 \mathrm{~mm}(\mathrm{sd}=19.7, \mathrm{n}=4)$.

Spring 1999: Fork lengths from 3,796 chinook ( $14.8 \%$ of the total catch) were measured during spring monitoring (Appendix 37). No Age 1 chinook were captured in 1999. Initial catches of Age 0 chinook occurred in JW $11(0=37 \mathrm{~mm}, \mathrm{n}=1)$. Mean fork lengths increased steadily throughout the trapping period. In JW 23 hatchery fish were first observed and comprised $5 \%$ of the catch that week. CPUE increased from 3 fish in JW 22 to a peak of 478 fish in JW 30. Upon the arrival of hatchery fish, mean weekly fork lengths increased from $62 \mathrm{~mm}(\mathrm{sd}=18.3, \mathrm{n}=133)$ to $72 \mathrm{~mm}(\mathrm{sd}=14.9, \mathrm{n}=189)$. Spring trapping concluded on JW 39 with a mean fork length $101 \mathrm{~mm}(\mathrm{sd}=7.3, \mathrm{n}=209)$

Spring and Fall 2000: Fork lengths from 3,911 chinook ( $16.5 \%$ of the total catch) were measured (Appendix 39). No yearling chinook were captured during 2000. Initial catches of Age 0 chinook occurred in JW 20 ( $0=59 \mathrm{~mm}, \mathrm{sd}=9.6, \mathrm{n}=78$ ). In JW 23 hatchery fish were first observed and comprised $20 \%$ of the catch that week. CPUE increased from 40 fish in JW 22 to a peak of 496 fish in JW 30. Upon the arrival of hatchery fish, mean weekly fork lengths increased from $70 \mathrm{~mm}(\mathrm{sd}=14.1, \mathrm{n}=202)$ to $84 \mathrm{~mm}(\mathrm{sd}=14.9, \mathrm{n}=210)$. Spring trapping concluded on JW 39 with a mean fork length of $103 \mathrm{~mm}(\mathrm{sd}=7.5, \mathrm{n}=170)$. Trapping was conducted for only one week (JW 40) during the fall season. Catch numbers for hatchery Age 0 chinook increased while natural Age 0 chinook catch numbers decreased. The mean fork length for JW 40 was $117 \mathrm{~mm}(\mathrm{sd}=20.1, \mathrm{n}=150)$.

Figure 7. Chinook Age 0 and Age 1 mean fork lengths (mm) by Julian week at the WCT, 1997-2000.
(+/- 1 standard error, sample size)

Chinook Abundance Index and Hatchery Contributions by Year - Spring Monitoring

Spring 1997: Monitoring at the WCT started in late March (JW 13). Initial catches were small and consisted largely of natural Age 0 chinook. Several Age 1 chinook were captured early in the trapping season (JW 13-JW 22). Catches increased weekly throughout the months of April and May, with the peak weekly catch occurring in the beginning of July (JW 28). Hatchery Age 0 chinook contributions began during JW 24 and peaked in JW 28 (Figure 8). Monitoring at the WCT continued throughout the spring and into the fall season. The spring 1997 WCT abundance index total was 397,558 (Appendix 13).

Spring 1998: Spring monitoring at the WCT began in mid-April (JW 16), with few natural Age 0 chinook being captured before the middle of June (JW 25). Catches increased weekly throughout the months of June and July, with the peak weekly catch occurring in the end of July (JW 31). Hatchery Age 0 chinook contributions began during JW 25 and peaked in JW 31 (Figure 8). Spring monitoring at the WCT concluded at the end of August (JW 39). The spring 1998 WCT abundance index was 910,729 (Appendix 16).

Spring 1999: Spring monitoring at the WCT began in mid-March (JW 11), with few natural Age 0 chinook being captured before early June (JW 23). Catches increased weekly throughout the months of June and July, with the peak weekly catch occurring in the end of July (JW 30). Hatchery Age 0 chinook contributions began during JW 23 and peaked in JW 31 (Figure 8). Spring monitoring at the WCT concluded at the end of August (JW 39). The spring 1999 WCT abundance index was 544, 172 (Appendix 19).

Spring 2000: Spring monitoring at the WCT began in mid-May (JW 20), with few natural Age 0 chinook being captured before late May (JW 22). Catches increased weekly throughout June and July with the peak weekly catch occurring in late July (JW 30). Hatchery Age 0 chinook contributions began during early JW 23 and peaked in JW 29 (Figure 8). Spring monitoring at the WCT concluded at the end of August (JW 39). The spring 2000 WCT abundance index was 451,212 (Appendix 22).

Chinook Abundance Index and Hatchery Contributions by Year - Fall Monitoring
Fall 1997: Fall monitoring at the WCT began in early October (JW 40). Natural Age 0 catch numbers dramatically increased in the first week of fall trapping with the peak weekly catch occurring in the second week of October (JW 41). Hatchery Age 0 chinook contributions increased during JW 40 and peaked in JW 41. Monitoring at the WCT concluded in the beginning of December JW 49 (Appendix 13). The fall 1997 WCT abundance index was 172,849 .

Fall 1998: Fall monitoring on the WCT began in early October (JW 40). Natural age 0 catch numbers initially decreased but peaked in mid-October (JW 41). Hatchery Age 0 contributions increased during JW 40 with the peak weekly catch occurring in mid-October (JW 41). Monitoring at the WCT concluded in mid-November (JW 47) (Appendix 16). The fall 1998 WCT abundance index was 327,224.

Fall 1999: No Fall monitoring on the WCT occurred in 1999 (Appendix 19).
Fall 2000: The Fall monitoring on the WCT consisted of six trapping days in JW 40. The abundance index for this period was 4,957 (Appendix 22).

Figure 8. Weekly abundance index totals for natural and hatchery chinook at the WCT, spring 1997-2000.

## Emigration Timing

Like the BBT, very few natural Age 0 chinook were captured prior to the beginning of June (JW 23). This trend was consistent for all four years (Figure 9). However, unlike the BBT, natural chinook emigration occurred earlier in 1999 and 2000 compared to 1997 and 1998. Water temperatures reached $15^{\circ} \mathrm{C}$ in early May 1997, early June 1998, late May 1999, and late May 2000. The maximum of flows in June 2000 (range 1,900$3,300 \mathrm{cfs}$ ) were lower than June 1999 (range 2,500-5,600 cfs), June 1998 (range 6,000-12,100 cfs) or June 1997 (1,400-4,100 cfs) (Figure 10).

Figure 9. Emigration timing of natural (A) and TRH released chinook (B) at the WCT, spring 1997-2000.

Figure 10. Mean daily flow (cfs) at Hoopa and mean daily river temperature $\left({ }^{\circ} \mathrm{C}\right)$ at the WCT, 1997-2000.

## Intra Basin Comparison

Flows in the Trinity River were generally higher than the Klamath River during most of the periods both traps were operating. Mean daily water temperatures (MDT) were slightly lower in the Klamath River for most of the period both traps were operating (Figure 11). The MDT of both rivers exceeded "stressful conditions" $\left(>20^{\circ} \mathrm{C}\right)$ by the beginning of July (JW 27) or sooner. Water temperatures on the Trinity would often return to below $20^{\circ} \mathrm{C}$ by the beginning of August (JW 35). The Klamath trap was removed before temperatures had dropped below $20^{\circ} \mathrm{C}$.

On both rivers, the bulk of the 1997-2000 natural Age 0 chinook emigration corresponded with periods of rapidly increasing water temperatures. Most chinook had emigrated past the traps before MDTs reached stressful levels. The peak of the Klamath River natural Age 0 chinook emigration is often more pronounced and larger in magnitude than in the Trinity River. However, Age 0 emigration tapered off faster in the Klamath River than in the Trinity River.

Winter storms in late December 1996 and early January 1997, produced a high flow event and peak flow of 233,000 cfs recorded at Orleans on January 1, 1997 (Figure 6). Intermittent storms in 1998, produced two high flow events, 80,200 cfs in mid-January, and 95,400 in late March and storms in the fall of 1998 resulted in high flows in November and December (Figure 6). The magnitude and timing of these November/December flow events may have resulted in scouring of fall chinook and coho redds. A peak flow of $52,700 \mathrm{cfs}$ occurred in early March 1999 (Figure 6). In 2000 a peak flow of only 34,500 cfs occurred in mid January.

High flow events occurring in December and January can scour salmon redds resulting in poor egg-to-fry survival. Conversely, moderate to low flows in December and January will result in little or no negative effects to salmon egg-to-fry survival. Steelhead spawn in early spring, primarily in tributaries. The effects of high spring flows and steelhead egg-to-fry survival is not well understood. However, the protracted spawning period into late spring/early summer may reduce negative impacts. High winter flows, snowpack and subsequent spring runoff conditions, summer meteorological conditions, and smoke due to forest fire, all contribute to the yearly variability observed in the timing and duration of salmonid outmigration in spring/summer.

Figure 11. Mean daily Klamath and Trinity river temperatures $\left({ }^{\circ} \mathrm{C}\right)$ at the BBT and WCT sites during the period of peak chinook Age 0 emigration, 1997-2000.

## Additional Salmonid Catches

The capture of additional salmonid species (steelhead, coho, chum) were incidental to the capture of chinook juveniles, which was the primary objective of this monitoring project. Results reflect emigration trends during periods of coemigration with juvenile chinook.

Klamath River Coho

As in previous years, coho catches at the BBT from 1997 to 2000 were very low. Typically, coho smolts (age $1+$ ) were captured in early May to mid-June, and coho Age 0 from late February to early July. Coho smolts age $1+$ were released from IGH during late-March for all monitoring periods in 1997-2000. IGH released between 74,250 and 150,312 age $1+$ coho smolts during the 1997-2000 monitoring period, (Table 9).

Table 9. Iron Gate Hatchery coho releases, 1997-2000.

|  |  |  | Release \# and Mark |  | Total |
| :---: | :---: | :---: | ---: | ---: | ---: |
| Brood Year \& age | Date of <br> Release | Size <br> (grams) | Left <br> released |  |  |
| coho-95 2+ | $4 / 11 / 1997$ | 10 | 74,250 | 0 | 74,250 |
| coho-96 2+ | $3 / 30 / 1998$ | 41.2 | 79,607 | 0 | 79,607 |
| coho-97 $2+$ | $3 / 30 / 1999$ | 37.8 | 146,858 | 3,454 | 150,312 |
| coho-98 $2+$ | $3 / 30 / 2000$ | NA | 77,147 | 0 | 77,147 |

## Coho Catches

A total of 152 coho (natural and hatchery) were captured at the BBT during the four spring monitoring periods (Table 10). Age 0 coho comprised $71 \%$ of the total four year catch. Natural age $1+$ fish comprised $20 \%$ and hatchery fish comprised $9 \%$ of the total four year catch. No Fall trapping operations were conducted on the Klamath River from 1997-2000.

Table 10. BBT coho catch numbers by age, Spring monitoring, 1997-2000.

|  | Days | Coho |  |  |  | \% of Total |  |  |
| :---: | :---: | ---: | ---: | ---: | ---: | :---: | :---: | :---: |
| Year | trappe | Nat Age 1 | Hat Age 1 | Nat Age 0 | Total | \% Nat 1 | \% Hat 1 | \% Nat 0 |
| 1997 | 126 | 17 | 3 | 13 | 33 | $52 \%$ | $9 \%$ | $39 \%$ |
| 1998 | 97 | 1 | 2 | 12 | 15 | $7 \%$ | $13 \%$ | $80 \%$ |
| 1999 | 118 | 4 | 6 | 38 | 48 | $8 \%$ | $13 \%$ | $79 \%$ |
| 2000 | 92 | 8 | 3 | 45 | 56 | $14 \%$ | $5 \%$ | $80 \%$ |
| Totals |  | 30 | 14 | 108 | 152 | $20 \%$ | $9 \%$ | $71 \%$ |

## Abundance Index and Hatchery Contributions

The total (fry, parr, smolt) coho abundance index for spring monitoring 1997-2000, ranged from 4,805 to 6,918, with the largest abundance index total occurring in spring 1999 (Figure 12). Hatchery contributions ranged from 6 to 17 percent with the greatest number occurring in 1998 (Table 11). All IGH coho were tagged with a left maxillary clip in 1997, 1998 and 2000. In 1999, $97 \%$ of the IGH coho received left maxillary clips, the remaining $3 \%$ were released unmarked.

Table 11. BBT coho abundance index by age, Spring monitoring, 1997-2000.

|  | Days | Coho |  |  |  | \% of Total |  |  |
| :--- | :---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Year | trapped | Nat Age 1 | Hat Age 1 | Nat Age 0 | Total | \% Nat 1 | \% Hat 1 | \% Nat 0 |
| 1997 | 126 | 1,268 | 196 | 811 | 2,275 | $56 \%$ | $9 \%$ | $36 \%$ |
| 1998 | 97 | 160 | 368 | 1,580 | 2,108 | $8 \%$ | $17 \%$ | $75 \%$ |
| 1999 | 118 | 457 | 885 | 5,576 | 6,918 | $7 \%$ | $13 \%$ | $81 \%$ |
| 2000 | 92 | 799 | 284 | 3,722 | 4,805 | $17 \%$ | $6 \%$ | $77 \%$ |
| Totals |  | 2,684 | 1,733 | 11,689 | 16,106 | $17 \%$ | $11 \%$ | $73 \%$ |

Fork length and emigration timing

Spring 1997: A total of 32 coho were measured in 1997, between JW 17 and 27 (Appendix 25). Coho Age 0 were first observed during JW 17 with a mean fork length of $68 \mathrm{~mm}(\mathrm{sd}=16.9, \mathrm{n}=2)$ (Figure 13). The last Age 0 coho was captured during JW 27 with a fork length of 63 mm . Age 1 coho were captured throughout JW 17-24. The mean fork length during this period ranged from 100 to 180 mm . Hatchery coho were captured beginning JW 19 through JW 22, with fork lengths ranging from 132 to 165 mm (Figure 13).

Spring 1998: A total of 15 coho were measured in 1998, between JW 18 and 28 (Appendix 27). Coho Age 0 were first observed during JW 18 with a mean fork length of $63 \mathrm{~mm}(\mathrm{sd}=10.6, \mathrm{n}=2$ ) (Figure 13). The last Age 0 coho was captured during JW 28 with a fork length of 54 mm . Only one age 1 coho was captured during JW 24 with a fork length of 115 mm . Two hatchery coho were captured during JW 21 and 24 which measured 252 and 175 mm respectively (Figure 12).

Spring 1999: A total of 55 coho were measured in 1999, between JW 16 and 30 (Appendix 29). Coho Age 0 were first observed during JW 16 with a mean fork length of $35 \mathrm{~mm}(\mathrm{sd}=2.1, \mathrm{n}=2$ ) (Figure 13). The last Age 0 coho was captured during JW 30 with a fork length of 76 mm . Age 1 coho were captured during JW 22 and JW 25. The fork lengths of these fish ranged from 153 mm to 164 mm . Hatchery coho were captured beginning JW 22 through JW 24, with fork lengths ranging from 153 to 164 mm (Figure 12).

Spring 2000: A total of 56 coho were measured in 2000, between JW 16 and 26 (Appendix 31). Coho Age 0 were first observed during JW 16 with a mean fork length of $48 \mathrm{~mm}(\mathrm{sd}=23.79, \mathrm{n}=3)$ (Figure 13). The last Age 0 coho was captured during JW 26 with a mean fork length of $70 \mathrm{~mm}(\mathrm{sd}=.58, \mathrm{n}=3)$. Age 1 coho were captured during JW 18 and JW 22. The fork lengths of these fish ranged from 110 mm to 146 mm . Hatchery coho were captured during JW 18 and JW 20, with fork lengths ranging from 147 to 183 mm (Figure 12).

Figure 12. Weekly abundance index totals for natural and hatchery coho at the BBT, 1997-2000.

Figure 13. Natural coho Age 0 and Age 1 mean fork lengths (mm) by Julian week at the BBT, 1997-2000. (+/1 standard error, sample size).

## Klamath River Steelhead

Fry, parr and smolt life history phases of natural steelhead juveniles were captured at the BBT during spring monitoring. IGH steelhead are typically reared one year and released in mid-May. In 1997 no steelhead release occurred. In $1998100 \%$ of age $1+$ steelhead were released with adipose clips. In 1999, $50 \%$ of age $1+$ steelhead received AD and left maxillary clips. In $2000100 \%$ of age $1+$ steelhead received AD and right maxillary clips (Table 12).

Table 12. Iron Gate Hatchery steelhead releases, 1997-2000.
( $\mathrm{AD}-\mathrm{LM}=$ adipose and left maxillary clip, $\mathrm{AD}-\mathrm{RM}=$ adipose and right maxillary clip).

| Brood Year \& age | Date of Release | $\begin{gathered} \text { Size } \\ \text { (grams) } \end{gathered}$ | Release \# and mark |  |  |  | Total released |

## Steelhead Catches

A total of 1,342 steelhead (natural and hatchery) were captured at the BBT during the four spring monitoring periods (Table 13). YOY steelhead comprised $34 \%$ of the total four year catch. Fish of age 1,2 and 3 comprised 37, 27 and 2 percent of the combined catch, respectively. No Fall trapping operations were conducted at the BBT during 1997-2000.

## Abundance Index and Hatchery Contributions

The total steelhead abundance index for spring monitoring 1997-2000, ranged from 14,456 to 66, 125 fish, with the largest abundance index total occurring in spring 1998 (Table 14). Hatchery contributions were small, ranging from 0 to 1 percent of each years catch. Natural Age 1 steelhead comprised the majority of the steelhead index.

Table 14. BBT steelhead abundance index by age, Spring monitoring, 1997-2000.

|  | Steelhead |  |  |  |  |  | \% of Total |  |  |  |  |  |

Spring 1997: A total of 386 steelhead were measured in 1997, between JW 13 and 34 (Appendix 26). Steelhead Age 0 were first observed during JW 21 with a mean fork length of 41 mm ( $\mathrm{sd}=7.5, \mathrm{n}=4$ ). Trapping concluded on JW 34 at which time, Age 0 mean fork length had increased to 70 mm ( $\mathrm{sd}=12.4, \mathrm{n}=12$ ). Age 1 steelhead were captured throughout the monitoring period. Age 1 mean fork lengths during the beginning of trapping (JW 13) were $82 \mathrm{~mm}(\mathrm{sd}=10.6, \mathrm{n}=2$ ). By the conclusion of the trapping period (JW 34), Age 1 mean fork lengths were 134 mm ( $\mathrm{sd}=4.8, \mathrm{n}=4$ ). Mean fork lengths for Age 2 and Age 3 steelhead did not show a consistent increase during the monitoring period. Age 2 mean weekly fork lengths ranged from 149 to 191 mm ( $\mathrm{sd}=17.3, \mathrm{n}=59$ ). Age 3 mean fork lengths ranged from 219 to 250 mm ( $\mathrm{sd}=13.6, \mathrm{n}=4$ ) (Figure 14). Only one hatchery steelhead was captured during 1997.

Spring 1998: A total of 428 steelhead were measured in 1998, between JW 18 and 33 (Appendix 28). In 1998 no steelhead age class showed a consistently increasing length frequency. Age 0 mean weekly fork lengths ranged from 53 to $83 \mathrm{~mm}(\mathrm{sd}=13.7, \mathrm{n}=83)$. Age 1 mean weekly fork lengths ranged from 111 to $149 \mathrm{~mm}(\mathrm{sd}=16$, $\mathrm{n}=115$ ). Age 2 mean weekly fork lengths ranged from 152 to 190 mm ( $\mathrm{sd}=18.9, \mathrm{n}=221$ ). Age 3 mean weekly fork lengths ranged from 229 to $248 \mathrm{~mm}(\mathrm{sd}=11.5, \mathrm{n}=9)$. No hatchery steelhead were observed during 1998 (Figure 14).

Spring 1999: A total of 302 steelhead were measured in 1999 between JW 18 and 33 (Appendix 30). In 1998 no steelhead age class showed a consistently increasing length frequency. Age 0 mean weekly fork lengths ranged from 41 to $59 \mathrm{~mm}(\mathrm{sd}=12, \mathrm{n}=98)$. Age 1 mean weekly fork lengths ranged from 53 to $197 \mathrm{~mm}(\mathrm{sd}=53.4$, $\mathrm{n}=165$ ). Age 2 steelhead mean fork lengths ranged from 132 to $181 \mathrm{~mm}(\mathrm{sd}=37.6, \mathrm{n}=39)$. No Age 3 or hatchery steelhead were observed during 1998 (Figure 14).

Spring 2000: A total of 137 steelhead were measured in 2000, between JW 14 and 29 (Appendix 32). Steelhead Age 0 were first observed during JW 17 with a fork length of $43 \mathrm{~mm}(\mathrm{n}=1)$. Trapping concluded on JW 29 at which time, Age 0 mean weekly fork length had increased to 52 mm ( $\mathrm{sd}=8.5, \mathrm{n}=2$ ). Age 1 steelhead were captured throughout the monitoring period. Age 1 mean weekly fork lengths at the beginning of trapping (JW 14) were $77 \mathrm{~mm}(\mathrm{sd}=8.3, \mathrm{n}=4)$. By the conclusion of the trapping (JW 29), Age 1 mean weekly fork lengths were 153 mm ( $\mathrm{sd}=2.7, \mathrm{n}=3$ ). The mean weekly fork lengths for age 2 and age 3 steelhead did not show a consistent increase during the monitoring period. Age 2 mean weekly fork lengths ranged from 156 to 222 mm $(\mathrm{sd}=41.8, \mathrm{n}=51)$. Age 3 mean fork lengths ranged from 217 to $247 \mathrm{~mm}(\mathrm{sd}=18.4, \mathrm{n}=10)$ (Figure 14). Only one hatchery steelhead was captured during 2000.

Figure 14. Mean lengths-at-age, standard deviation, and sample size by Julian week for natural steelhead at the BBT, 1997-2000.

## Trinity River Coho

Trinity River coho catch numbers were significantly higher than those of the BBT. Coho smolts (Age $1+$ ) were captured in early May to mid-June, and coho Age 0 from late February to early July. Coho smolts Age 1+ were released from Trinity River Hatchery during mid to late March in 1997 through 2000. TRH released smolts between 69,993 and 516,192 age $1+$ coho smolts during the 1997-2000 monitoring period (Table 15).

Table 15. Trinity River Hatchery coho releases, 1997-2000.

## Coho Catches

A total of 2,813 coho (natural and hatchery) were captured at the WCT during the four spring monitoring periods (Table 16; Appendix 14, 17, 20, and 23). Age 0 coho comprised $12 \%$ of the total four year catch. Natural Age 1 and hatchery Age 1 coho comprised the majority of the total catch ( $79 \%$ and $9 \%$ respectively). Four Age 0 coho were captured during the fall monitoring period in 1997 and 1998.

Table 16. WCT coho catch by age, Spring and Fall monitoring, 1997-2000.

| Year | Days <br> Fished | Coho |  |  |  | \% of Total |  |  |

## Abundance Index and Hatchery Contribution

The total coho abundance index for spring monitoring 1997-2000, ranged from 8,576 to 108,995 with the largest abundance index total occurring in spring 1999. Hatchery contributions were much larger on the Trinity River, ranging from 62 to 92 percent with the greatest number occurring in 1998 (Table 17). All coho were tagged with a right maxillary clip for 1997 through 2000 (Table 15).

Table 17. WCT coho abundance index by age, Spring and Fall monitoring, 1997-2000.

|  | Days <br> Year | Coho |  |  |  |  | \% of Total |  |  |

Fork length and emigration timing

Spring and Fall 1997: A total of 609 coho were measured in 1997, between JW 13 and 49 (Appendix 33). Coho Age 0 were first observed during JW 18 with a mean fork length of 49 mm ( $\mathrm{sd}=1.0, \mathrm{n}=3$ ) (Figure 15). The last Age 0 coho was captured during JW 49 with a fork length of 85 mm . Age 1 coho were captured throughout JW 14-27. The fork lengths of these fish ranged from 100 to 191 mm . Hatchery coho ( $\mathrm{n}=446$ ) were captured from JW 13 through JW 29, with fork lengths ranging from 68 to 190mm (Figure 16).

Spring and Fall 1998: A total of 353 coho were measured in 1998, between JW 16 and 46 (Appendix 35). Coho Age 0 were first observed during JW 17 with a fork length of $47 \mathrm{~mm}(\mathrm{n}=1)$ (Figure 15). The last Age 0 coho was captured during JW 46 with a fork length of $93 \mathrm{~mm}(\mathrm{n}=1)$. Age 1 coho were captured during JW 24 through 35. The fork lengths of these fish ranged from 114 to 181 mm . Hatchery coho ( $\mathrm{n}=302$ ) were captured from JW 16 through JW 27, with fork lengths ranging from 115 to 275 mm (Figure 16).

Spring and Fall 1999: A total of 1,293 coho were measured in 1999, between JW 11 and 39 (Appendix 37). Coho Age 0 were first observed during JW 14 with a mean fork length of 36 mm ( $\mathrm{sd}=3.1, \mathrm{n}=3$ ) (Figure 15). The last Age 0 coho was captured during JW 39 with a fork length of $74 \mathrm{~mm}(\mathrm{n}=1)$. Age 1 coho were captured during JW 12 through JW 30. The fork lengths of these fish ranged from 95 to 188 mm . Hatchery coho (1039) were captured from JW 11 through JW 27, with fork lengths ranging form 100 to 250 mm (Figure 16).

Spring and Fall 2000: A total of 159 coho were measured in 2000, between JW 20 and 39 (Appendix 39). The first Coho Age 0 was first observed during JW 21 with a fork length of 58 mm ( $\mathrm{n}=1$ ) (Figure 15). The last Age 0 coho was captured during JW 35 with a fork length of $104 \mathrm{~mm}(\mathrm{n}=1)$. Age 1 coho were captured during JW 19 through JW 39. The fork lengths of these fish ranged from 99 to 158 mm . Hatchery coho ( $\mathrm{n}=83$ ) were captured during JW 20 through JW 24, with fork lengths ranging from 110 to 210 mm (Figure 16).

Figure 15. Weekly abundance index totals for natural and hatchery coho at the WCT, 1997-2000.

Figure 16. Coho Age 0 and Age 1 mean fork lengths (mm) by Julian week at the WCT, 1997-2000. (+/-1 standard error, sample size).

## Trinity River Steelhead

All life history phases of natural and hatchery steelhead juveniles were captured at the WCT during spring and fall monitoring. Trinity River Hatchery steelhead are typically reared one year and released in mid-May. In 1997 no steelhead release occurred. In 1998 through 2000 between 9,163 and 811,513 steelhead were released (Table 18).

Table 18. Trinity River Hatchery steelhead releases, 1997-2000.
( $\mathrm{AD}=$ adipose clip)

| Brood Year \& age | Date of Release | $\begin{gathered} \text { Size } \\ \text { (grams) } \end{gathered}$ | Release \# and Mark |  | Total released |

## Steelhead Catches

A total of 6,988 steelhead (natural and hatchery) were captured at the WCT during the four spring monitoring periods. Age 0 comprised between $38 \%$ to $60 \%$ of the yearly catch. Age 1 steelhead comprised between $21 \%$ to $33 \%$ of the yearly catch. Age 2 steelhead comprised between $10 \%$ to $27 \%$ of the yearly catch. Age 3 steelheaed comprised only 0 to $2 \%$ of the total catch (Table 19).

Table 19. WCT steelhead catch by age, Spring and Fall monitoring, 1997-2000.

## Abundance Index and Hatchery Contributions

The total steelhead abundance index for spring monitoring 1997-2000, ranged from 27,213 to 158,684 , with the largest abundance index total occurring in spring 1999 (Table 20). No clear trend was apparent from the percent change in age class for a given spring period.

Table 20. WCT steelhead abundance index by age, Spring and Fall monitoring 1997-2000.

| Date | Steelhead |  |  |  |  |  | \% of Total |  |  |  |  |  |

## Fork length and Emigration Timing

Steelhead Age 1 emigration timing ranged from March to June in the 1997-2000 monitoring period (Appendix 15, 18, 21, and 24). Fifty percent of Age 1 steelhead had been observed by JW 18, 23, 19, and 22 respectively for 1997 , 1998, 1999 and 2000. By JW 28, 26, 25 and 32, $95 \%$ of Age 1 steelhead had been captured for 1997, 1998, 1999 and 2000.

Spring and Fall 1997: A total of 1,892 steelhead were measured in 1997, between JW 13 and 49. (Appendix 34) Steelhead Age 0 were first observed during JW 23 with a fork length of 54 mm . By the end of the monitoring period (JW 49) the Age 0 mean fork length had increased to 93 mm ( $\mathrm{sd}=23.6$, $\mathrm{n}=4$ ). Age 1 steelhead were captured throughout the monitoring period. The mean fork length during the beginning of trapping (JW 13) was $91 \mathrm{~mm}(\mathrm{sd}=18.7, \mathrm{n}=34)$. By the conclusion of the trapping period (JW 49) the mean fork length was $139 \mathrm{~mm}(\mathrm{sd}=11.3, \mathrm{n}=2)$. The mean fork lengths for Age 2 and Age 3 steelhead did not show a consistent increase during the monitoring period. Age 2 mean fork lengths ranged from 150 to 220 mm . Age 3 mean fork lengths ranged from 209 to 274 mm . Hatchery steelhead were captured between JW 13 and JW 40. Hatchery fork lengths ranged from 130 to 248 mm (Figure 17). No Age 2 hatchery fish were captured.

Spring and Fall 1998: A total of 1,074 steelhead were measured in 1998, between JW 16 and 47 (Appendix 36). Steelhead Age 0 were first observed during JW 22 with a fork length of 49 mm . By the end of the monitoring period (JW 47) the Age 0 mean fork length had increased to 70 mm ( $\mathrm{sd}=9.8, \mathrm{n}=13$ ). Age 1 steelhead were captured throughout the monitoring period. The mean fork length during the beginning of trapping (JW 16) was 88 mm ( $\mathrm{sd}=22.9, \mathrm{n}=7$ ). By the conclusion of the trapping period (JW 47) the last steelhead captured measured 145 mm . The mean fork lengths for Age 2 and Age 3 steelhead did not show a consistent increase during the monitoring period. Age 2 mean fork lengths ranged from 132 to 220 mm . Age 3 mean fork lengths ranged from 225 to 280 mm . Hatchery steelhead were captured between JW 16 and JW 40. Hatchery fork lengths ranged from 117 to 275 mm . Two Age 2 hatchery fish were captured measuring 280 and 180 mm during JW 27 and 46 respectively (Figure 17).

Spring and Fall 1999: A total of 3,108 steelhead were measured in 1999 between JW 11 and 39 (Appendix 38). Steelhead Age 0 were first observed during JW 23 with a fork length of 44 mm . By the end of the monitoring period (JW 49) the Age 0 mean fork length had increased to 88 mm ( $\mathrm{sd}=13.4, \mathrm{n}=28$ ). Age 1 steelhead were captured throughout the monitoring period. The mean fork length during the beginning of trapping (JW 11) was 105 mm ( $\mathrm{sd}=15.1, \mathrm{n}=3$ ). By the conclusion of the trapping period (JW 40) the mean fork length was $140 \mathrm{~mm}(\mathrm{sd}=25.1, \mathrm{n}=10)$. The mean fork lengths for Age 2 and Age 3 steelhead did not show a consistent increase during the monitoring period. Age 2 fork lengths ranged from 72 to 261 mm . Age 3 fork lengths ranged from 170 to 400 mm . Hatchery steelhead were captured between JW 12 and JW 27. Hatchery fork lengths ranged from 133 to 254 mm

Spring and Fall 2000: A total of 859 steelhead were measured in 2000, between JW 20 and 40 (Appendix 40). Steelhead Age 0 were first observed during JW 21 with a fork length of $40 \mathrm{~mm}(\mathrm{n}=1)$. By the end of the monitoring period (JW 40) the Age 0 mean fork length had increased to 98 mm ( $\mathrm{sd}=15.7$, $\mathrm{n}=6$ ). Age 1 steelhead were captured throughout the monitoring period. The mean fork length during the beginning of trapping (JW 20) was $113 \mathrm{~mm}(\mathrm{sd}=31.9, \mathrm{n}=29)$. By the conclusion of the trapping period (JW 40) a fork length of 152 mm $(\mathrm{n}=1)$ was recorded. The mean fork lengths for age 2 and age 3 steelhead did not show a consistent increase during the monitoring period. Age 2 forklengths ranged from 119 mm to 215 mm . Age 3 mean fork lengths ranged from 129 mm to 210 mm . Hatchery age 1 fish were captured from JW 20 through JW 24 . Hatchery fork lengths ranged from 161 mm to 235 mm (Figure 17).

## Chum Salmon

A total of three juvenile chum salmon (Oncorhynchus keta) were captured during the four years of monitoring from 1997-2000. All three were captured from the Trinity River at Willow Creek on June 21, 1999. Fork lengths measured 37,38 and 40 mm . No other chum observations were recorded (Appendix 41-47).

Figure 17. Mean lengths-at-age, standard deviation, and sample size by Julian week for natural steelhead at the WCT, 1997-2000

## Non-target Species

Non-salmonid fish species captured in the Big Bar and Willow Creek rotary traps were enumerated and measured during both spring and fall of the monitoring period. The total catch for individual species varied greatly between years (Table 21), and much of this variation is likely attributable to trapping duration and discharge. One other factor that may have affected catch rates was the variation in trap placement. A total of 13,766 non-target fish were captured in the WCT. These were comprised of 13 species from 10 families. Total catch for the BBT was 3,729 fish comprised of 13 species from 9 families. Six introduced and six endemic species were captured at both the BBT and WCT. The BBT and WCT had four of the six introduced species in common (Appendix 41-Appendix 48).

Table 21. Season catch totals of non-target fish species captured at the BBT and the WCT, 1997-2000.

|  |  |  | Total number captured |  |  |  |  |  |  |  |  |  |  |

To account for variation in weekly trapping effort and discharge, abundance indices were calculated for the more abundant non-target species in the same manner as was done for the salmonids. As with the salmonids, validity of this abundance index is contingent upon the assumption that catch rates are directly proportional to the percentage of river flow sampled. For fish emigrating downstream, such as the salmonid smolts, this assumption seems reasonable. However, this may not be the case for other species that are not actively emigrating, or for fish that preferentially use different parts of the river..

Weekly abundance indices were higher in the early part of the trapping season for many species. Because flows are higher during this period (sometimes several orders of magnitude), the higher indices may simply represent higher rates of "passive" fish displacement rather than "active" emigration. A brief discussion on each of the more abundant non-salmonid species captured in the Big Bar and Willow Creek rotary traps follows.

Due to the difficulty in identifying sculpin species, this group was identified to genus only. Potentially up to four species of sculpin could have been collected, with prickly sculpin Cottus asper, the most likely sculpin to be caught in both rivers. The coastrange sculpin C. aleuticus is probably also present in both rivers, but it is seldom as abundant as the prickly sculpin when they occur together (Moyle 1976). Marbled sculpin C. klamathensis are reportedly widely distributed in the Klamath River, and the reticulate sculpin C. perplexus may occasionally be found in the lower Klamath (Moyle 1976).

Sculpin captures were highest in the early part of the trapping season on both rivers and during all years, (Figures 20-23). In general, prickly and coastrange sculpin typically migrate downstream to breeding areas between January and March and may spawn between February and June (Moyle 1976). Thus, the high abundance index values early in the season likely reflect breeding related activity.

Speckled dace capture trends and numbers were variable between years and traps. Dace numbers at the WCT were less that the BBT, but were more consistent throught the monitoring period. BBT dace numbers were greater that at WCT with a larger index being captured early in the monitoring period. Speckled dace numbers for 1997 at WCT and BBT do not show this trend. Catch numbers were larger and more consistent than 19982000, (Figures 20-23).

Four species of sucker are found in the Klamath drainage, Klamath smallscale sucker Catostomus rimiculus, Klamath largescale sucker C. snyderi, Lost River sucker C. luxatus, and shortnose sucker Chasmistes brevirostris (Moyle 1976). The Klamath smallscale sucker is the only sucker found in the Trinity River, and it is rare to find any other sucker species in the Klamath River below Klamath Falls (Moyle 1976). As such, all suckers captured were assumed to be of C. rimiculus species. Klamath largescale suckers are a relatively uncommon species found almost exclusively above Klamath Falls, though there are a few records for the lower Klamath River (Moyle 1976). Shortnose and Lost River suckers are confined to lakes and their tributaries in the upper Klamath drainage (Moyle 1976). Klamath smallscale suckers, almost all of which were juveniles, were the most frequently captured non-salmonid species at the WCT and second most captured at the BBT (Figures 20-23).

Threespine stickleback capture rates varied dramatically between rivers and monitoring years. On the Klamath, few sticklebacks were captured during 1997-2000. On the Trinity, stickleback captures were sporadic until May or June (JW 20-25) after which catches began to increase. Numbers peaked around August (JW 35). Stickleback numbers for the 1998 monitoring period on the Trinity do not conform to this trend (Figures 2023).

Three different life history stages of Pacific lamprey were captured: ammocetes, eyed juveniles, and adults. Pacific lamprey ammocetes are a non-parasitic larval stage that are categorized by lack of developed eyes. Most ammocetes were captured between April and July, (Figures 18 and 19). All ammocete larvae captured in the traps were most likely Age 0, which often move downstream with the current to areas of greater organic bottom debris, where they take up a filter feeding existence and remain buried several years as a larval stage ( $\mathrm{M}^{\mathrm{c}}$ Ginnis 1984). Metamorphosis to a macrophthalmia stage (obvious morphological change [i.e. eyes and lateral tooth plates]) marks the onset of parasitic feeding (Hardisty and Potter 1971, in Beamish 1980). Eyed juveniles were captured at both traps during their downstream migration throughout all trapping seasons. Catch numbers peaked in late May and early June (JW 18-24) for the BBT, while the peak of the WCT catch occurred during October to December, (JW 40-49) (Figures 18 and 19). Catch numbers for eyed juveniles were much greater for the periods of 1997 and 1998. Adult lamprey were captured during or following their spawning migration, primarily between late April (JW 17) and late July (JW 26), and looked to be in post-spawning condition (Figures 18 and 19).

American shad, a non-native anadromous species, spawn in the Trinity and Klamath Rivers annually. Live adults are rarely captured in the rotary traps but are commonly observed by crews in the late spring/early summer. Emigrating Age 0 were captured primarily between August (JW 32) and October (JW 44) on the Trinity River and very few on the Klamath.

Juvenile sturgeon were captured in two of the four monitoring periods at the WCT. Fifty nine juveniles were captured in 1997, sixteen in 1998, zero in 1999 and 2000. In 1997 captures occurred from mid May (JW 25) to late July (JW 31). In 1998 captures ranged from late July (JW 31) to mid October (JW 43). Total lengths ranged from 32 to 143 mm . Juvenile sturgeon were present in trap catches as late as October (JW 43). (Figures 20-23).

Juvenile sturgeon were captured in all four of the monitoring periods at the BBT. One hundred and twenty seven were captured in 1997, only nine were captured in 1997, eighty were captured in 1999, and only ten were captured in 2000. In all years captures ranged from early May (JW 18) to mid August (JW 33),
(Figures 20-23). Total lengths ranged from 22 to 400 mm .

## Recommendations

Rotary screw traps have proven to be an effective tool in assessing juvenile salmonid downstream migration. Traps can sample a large volume of water 24 hours a day, and can handle large amounts of debris. However, on large rivers such as the Klamath and Trinity, only a very small portion of the total river flow can be effectively sampled. Thus, an unknown portion of downstream migrants pass the traps unsampled, making it difficult to estimate the true population. Currently AFWO uses the trapping data to develop an abundance index that is used to compare relative abundance of fish caught at a particular site over time. The index method must be used because river flows, and thus the proportion of the flow sampled, vary daily. One assumption of the index is that the catch at the trapping site is directly proportional to the proportion of flow sampled. It is not known to what degree this assumption may be violated, but it likely depends on the trapping site. Currently, the abundance index does not account for other factors that may affect emigration and trapping efficiency, such as moon phase, temperature, turbidity, etc.

If known numbers of marked fish were released an appropriate distance above a trap each day the trap was operating, changes in flow, moon phase, temperature, turbidity, and other factors would not be an issue, and an actual population estimate could be made. The proportion of marked fish caught would then provide an estimate of trap efficiency for that particular day which could then be applied to the catch of unmarked fish to estimate the number of unmarked fish that passed the trap unsampled. The proportion of marked fish captured each day may vary according to a myriad of factors, but what those factors are and how much each one affects the catch does not need to be known to calculate the population estimate.

The AFWO has conducted varying numbers of efficiency tests each year at the WCT since 1989 (U.S. Fish and Wildlife Service 1991, 1992, 1994, 1998). Calculated efficiencies have ranged from $0 \%$ to $17.6 \%(0=3.61 \%)$. Several attempts to conduct efficiency tests on the Klamath River were aborted due to low catches, poor fish health and associated high mortalities (U.S. Fish and Wildlife Service 1991, 1992,).

A major obstacle to conducting valid efficiency tests on both rivers is lack of adequate fish capture in one day for a single marking event (U.S. Fish and Wildlife Service 1991, 1992, 1994, 1998). One or two day marking events have been desirable because of the extra manpower and equipment required to mark, transport, hold and release fish upstream, in addition to the regular trapping duties. Fish marked at the trap must be transported a sufficient distance upstream to allow random mixing with unmarked fish prior to their arrival at the trap. Also, the fish must be held in pens at the release site until dark.

One way to avoid many of the above problems would be to run two screw traps in the same river a relatively short distance apart. Fish captured at the upstream trap would be measured and marked (using a different mark each JW), then released. Captures of marked fish at the downstream trap would be used to calculate trap efficiency. This method was used successfully by Dempson and Stansbury (1991). The distance between the traps should be great enough to allow for random mixing of marked and unmarked fish, but close enough so that between trap mortality is negligible. It would also be desirable to have the traps far enough apart so that fish released in the morning or afternoon could not arrive at the trap before nightfall. One possibility would be to mark fish at the current WCT location and recapture somewhere downstream in the Hoopa Valley.

The AFWO recommends the continuation of annual rotary trapping programs to collect data used to assess: hatchery and natural contributions, salmonid abundance indices, size and emigration rate relationships and emigration duration. The traps also provide fish for health and disease assessment. Collecting abundance data on non-target species may also provide additional insight into the health of the Klamath River Basin.

The continuance of juvenile salmon monitoring may enable fisheries biologists a means of relating natural juvenile abundance indices and adult escapement estimates. Monitoring also provides information regarding the effects of water resource management policies on juvenile salmonid emigration. Such data are necessary for effectively implementing an "adaptive management" approach that will best meet the water needs of the fishery and various interests.
